

# Recent femtoscopic results from the STAR experiment

Adam Kisiel,  
Ohio State University

for the STAR Collaboration

37TH INTERNATIONAL SYMPOSIUM  
ON MULTIPARTICLE DYNAMICS

AUGUST 4 - 9, 2007  
LAWRENCE BERKELEY NATIONAL LABORATORY  
BERKELEY, CA

# Outline

---

- Continuing systematic studies:
  - Results for other energies
  - Different colliding systems
  - Multiplicity scaling
  - Volume scaling and constant mean free path at freeze-out
  - $k_T$  dependencies
  - Correlations with other pair types
- Expanding the field:
  - Studying two-particle interaction potentials
  - Non-identical particle correlations and the asymmetry measurement
  - Correlations with exotic particles
  - Correlations in small multiplicity systems

# The STAR Experiment

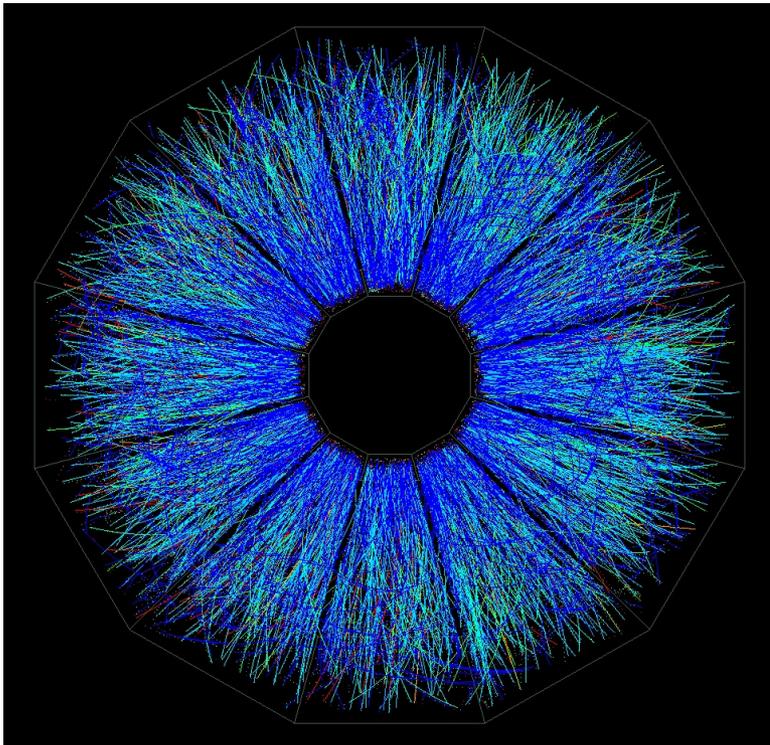

- Available datasets:

AuAu: 200 AGeV, 62 AGeV

CuCu: 200 AGeV, 62 AGeV

pp: 200 GeV

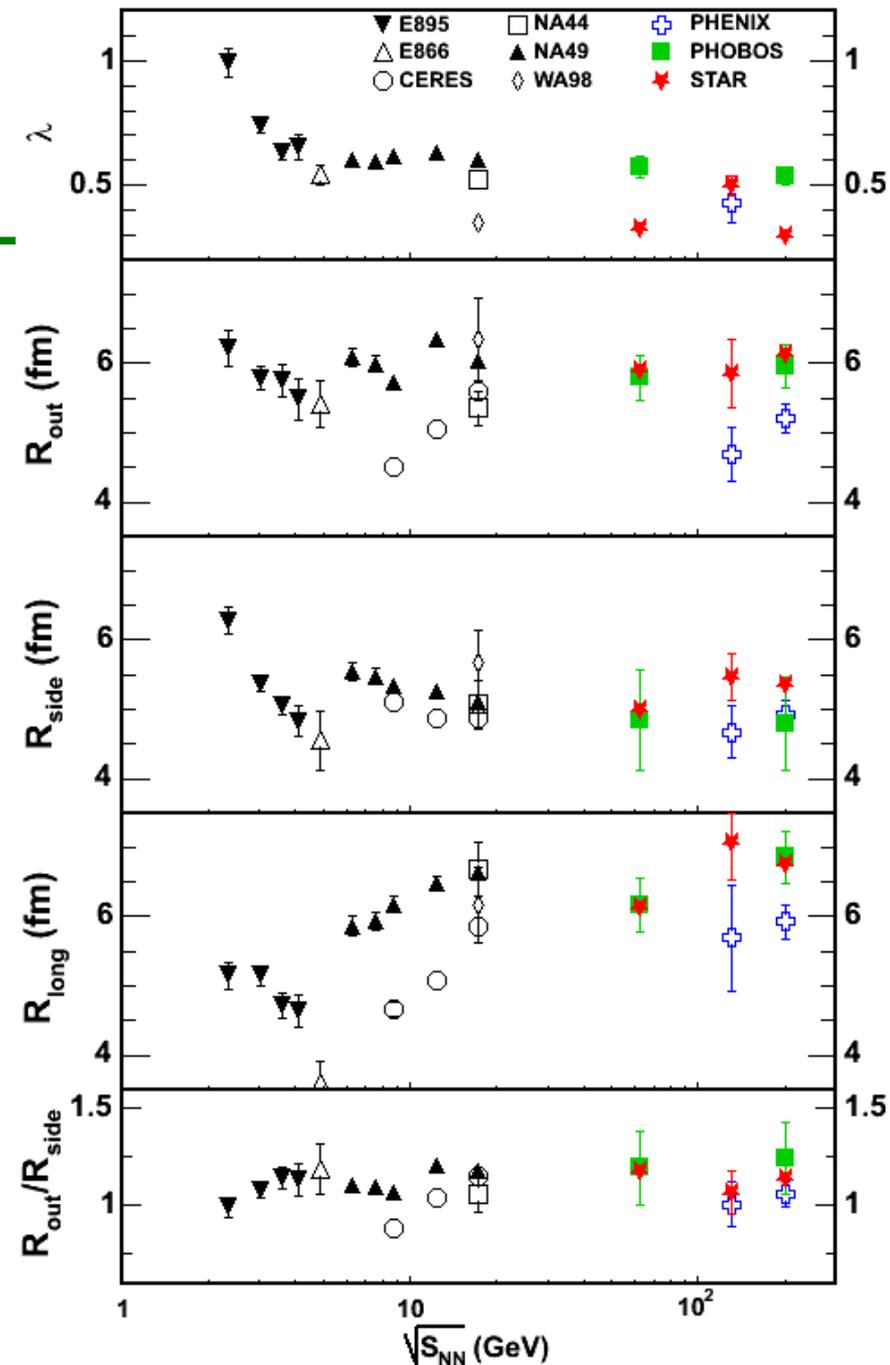

dAu: 200 AGeV

- 52 institutions from 12 countries
- Large acceptance TPC detector:  $-1 < y < 1$  and  $2\pi$  in azimuthal angle
- Pions, kaons and protons identified via  $dE/dx$  for  $p_T$   $0.12 - 1.2 \text{ GeV}/c$
- $V0$ 's identified by their decay topology

# HBT excitation function

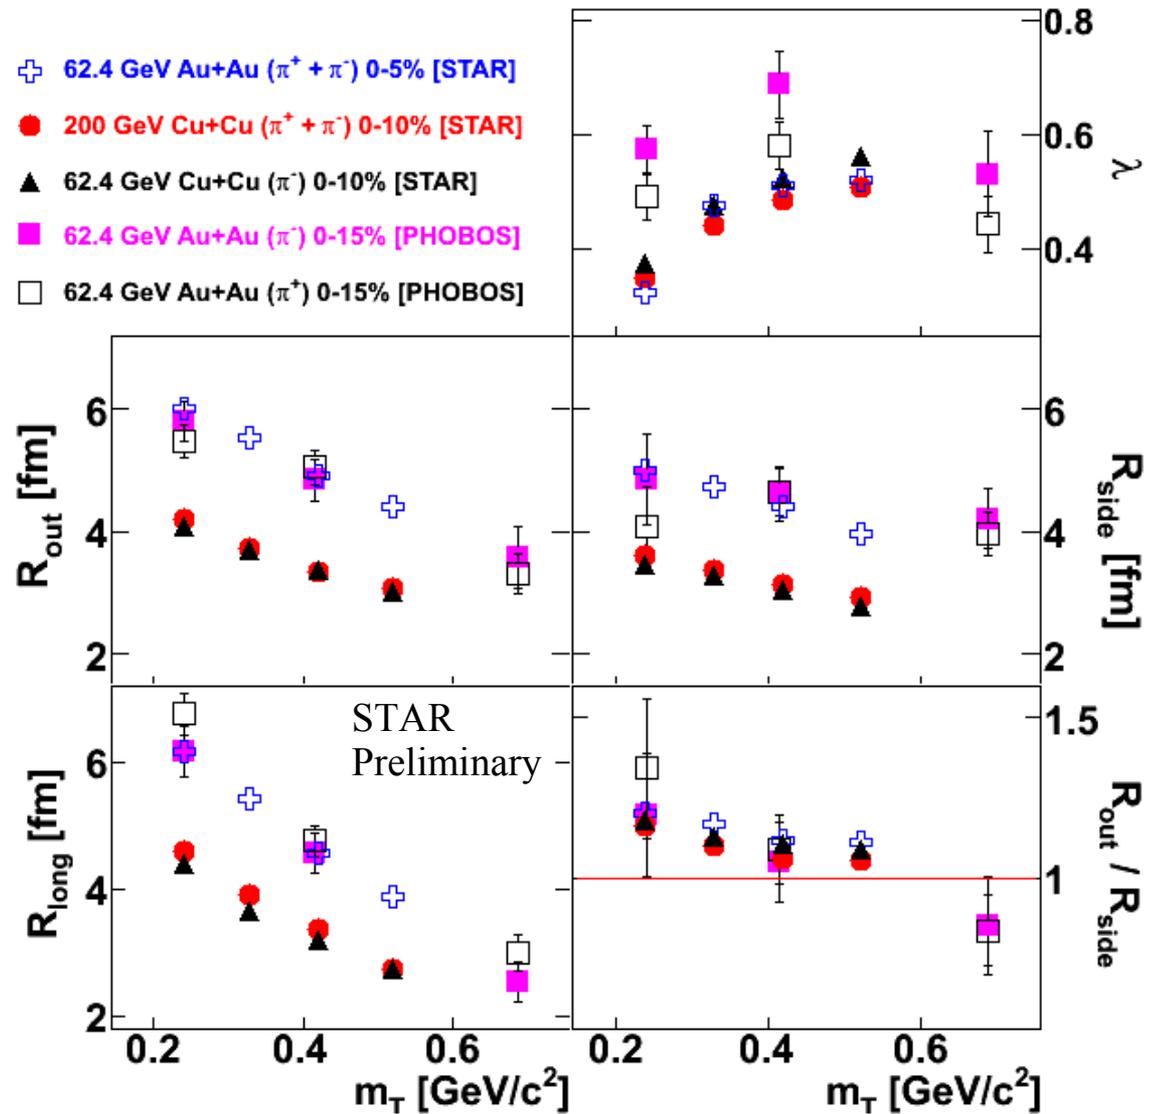

- No dramatic change in radii with energy of the collision observed in the RHIC energy range
  - Not consistent with “large-lifetime” scenario expected in the 1<sup>st</sup> order phase transition
  - How is it possible that 10x increase of energy does not change the size?

$$\mathbf{R}(\sqrt{s_{NN}}, \mathbf{m}_T, \mathbf{b}, N_{part}, A, B, \mathbf{PID})$$

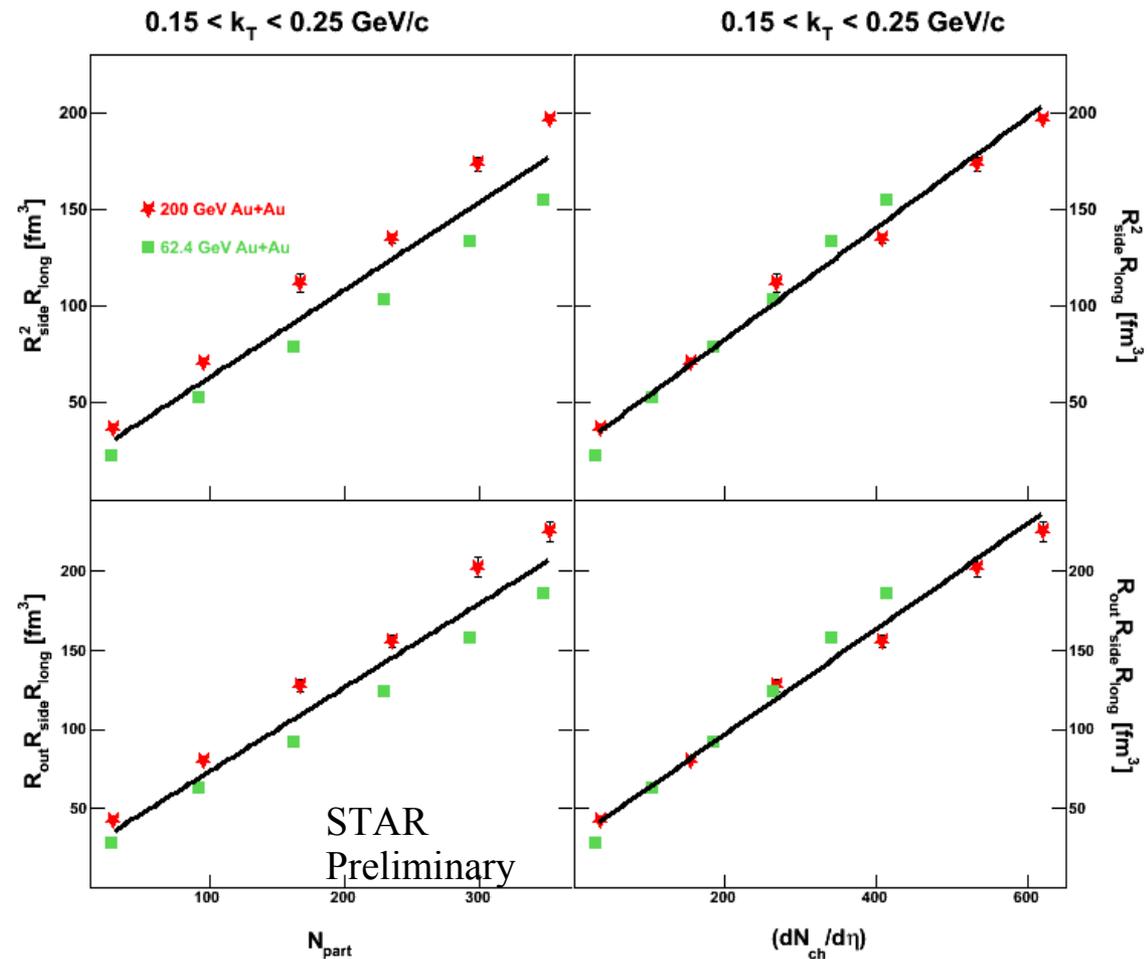

# CuCu and 62 GeV results

- Extending systematic study of pion femtoscopy
- Different collision energy and system type show patterns seen previously in AuAu.
- Both show strong radial flows and expected trend in radii vs. centrality and  $k_T$ .

# Searching for scaling laws

- Two scaling laws have been proposed for femtoscopic radii
- Our study shows that observed multiplicity is a better scaling variable than  $N_{\text{part}}$  – femtoscropy is final state (entropy) dominated

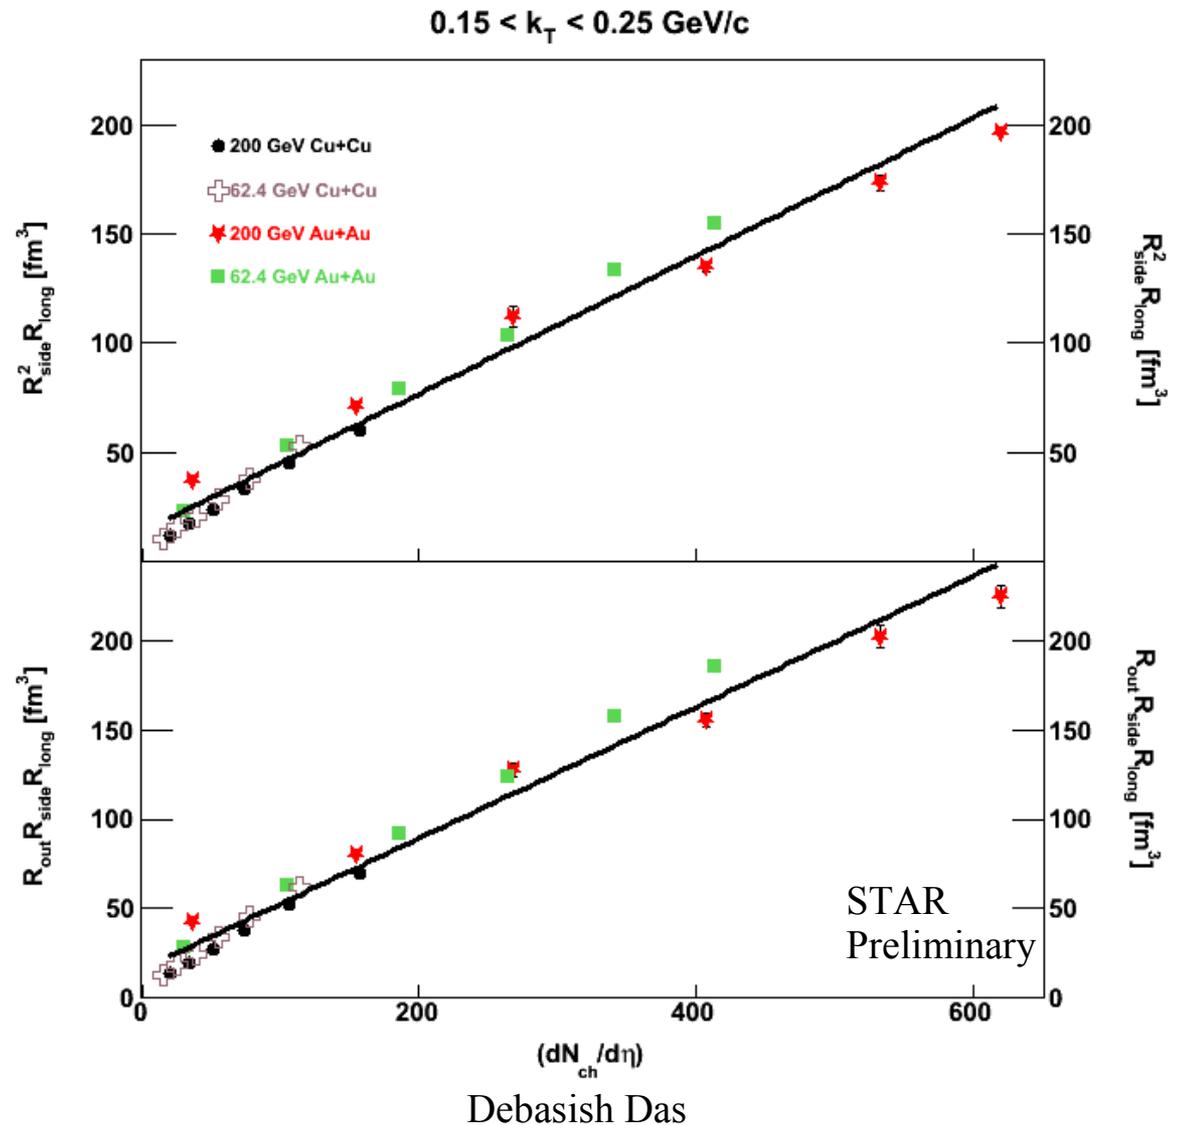

STAR  
Preliminary

Debasish Das

# Freeze-out at constant mean free path

- We plot all the measured systems vs. the scaling variable showing universality of the scaling
- The results suggests constant mean free path as a freeze-out criteria for pions

# Beyond HBT radii - source imaging

- Task imaging is to determine the source  $S(r)$  from data with errors  $C(q)$  by inverting the Koonin-Pratt equation

$$R(q) = C(q) - 1 = 4\pi \int r^2 \left( |\Phi_q^{(-)}(r)|^2 - 1 \right) S(r) dr$$

$$R(q) = 4\pi \int r^2 K(q, r) S(r) dr$$

requires the inversion of the interaction kernel  $K(q, r)$

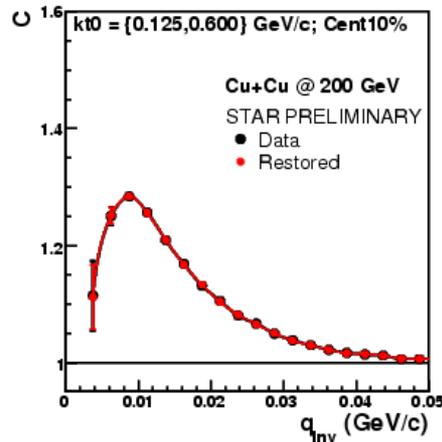

- Inversion procedure in matrix form, expansion in B-spline basis:

$$S(r) = \sum_j S_j B_j(r) \quad R_i^{Th} = \sum_j K_{ij} S_j \quad K_{ij} = 4\pi \int r^2 K(q, r) B_j(r) dr$$

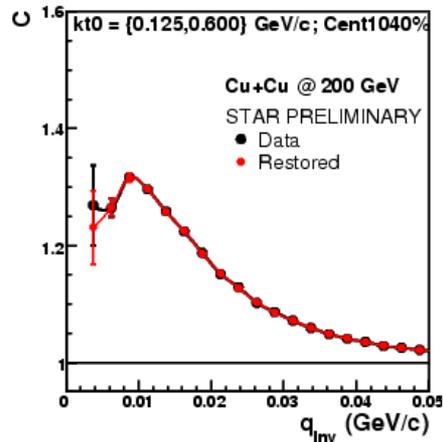

vary  $S_j$  to minimize  $\chi^2 = \frac{\sum_i (R_i - R_i^{Th})^2}{\Delta^2 R_i}$

# Imaging results

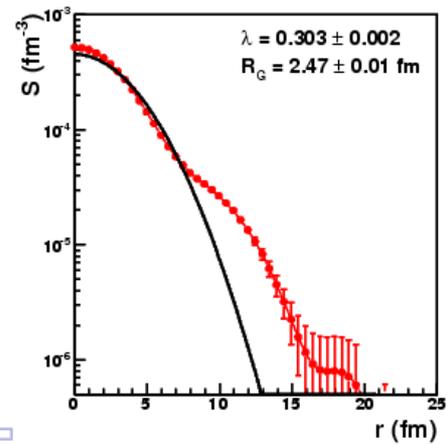

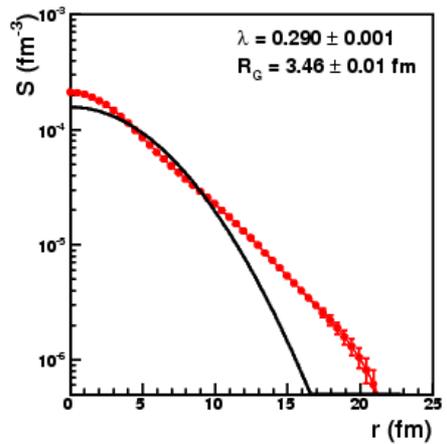

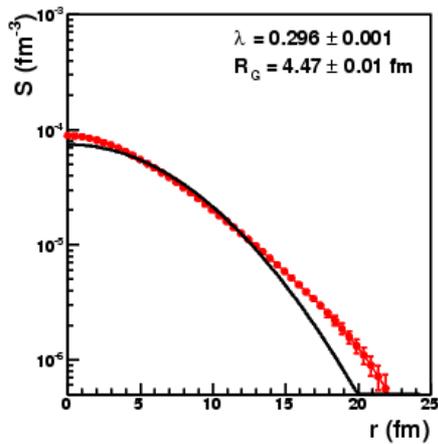

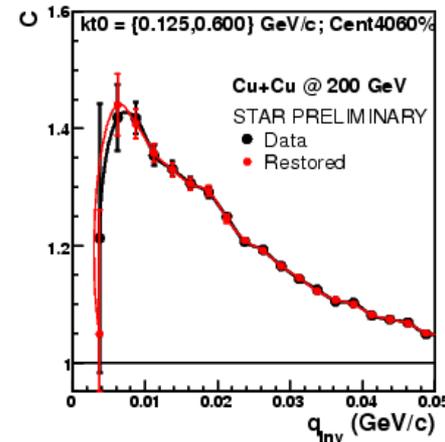

Centrality: 0–10%

10–40%

40–60%

- Imaging resolves non-gaussian long-range tail structures in the pion emission source

# Experimental situation for $a_0^0, a_0^2$

- ▶ DIRAC ( $A_{2\pi} : \pi^+\pi^- \rightarrow \pi^0\pi^0$ )  $\Rightarrow 1/\tau_{A_{2\pi}} \sim (a_0^0 - a_0^2)^2$
- ▶ NA48/2 ( $K_{3\pi} : K^\pm \rightarrow \pi^0\pi^0\pi^\pm$ )  $\Rightarrow (a_0^0 - a_0^2)$
- ▶ E865, NA48/2 ( $K_{e4} : K^\pm \rightarrow \pi^+\pi^-e^\pm\nu$ )  $\Rightarrow a_0^0$
- ▶ TRIUMF ( $\pi^+p \rightarrow \pi^+\pi^+n$ )  $\Rightarrow a_0^2$

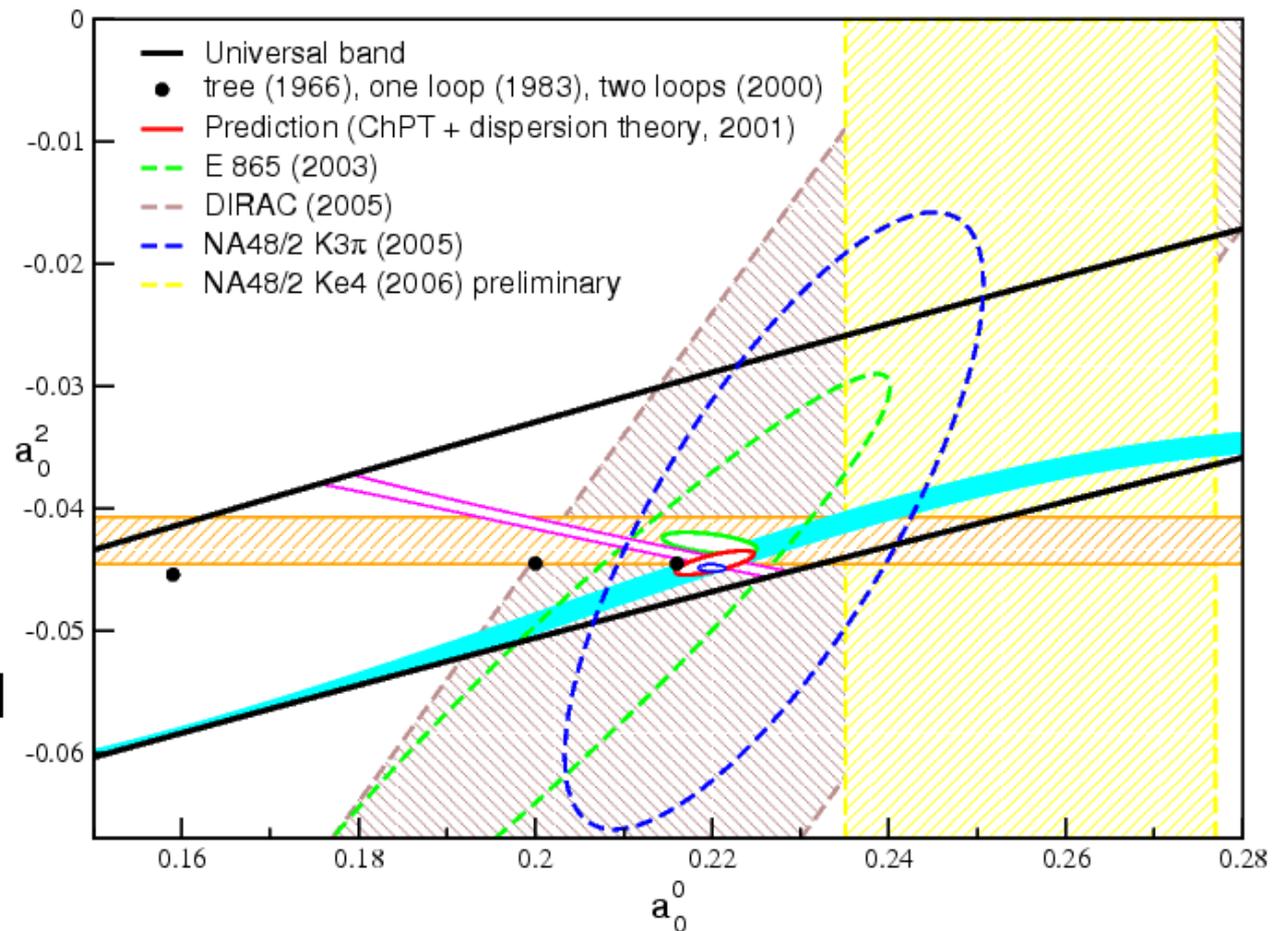

H. Leutwyler, Moriond 2007

ChPT prediction  
(Colangelo, Gasser,  
Leutwyler, hep-ph/0007112)

$$a_0^0 = 0.220 \pm 0.005 [m_\pi^{-1}]$$

$$a_0^2 = -0.0444 \pm 0.0010 [m_\pi^{-1}]$$

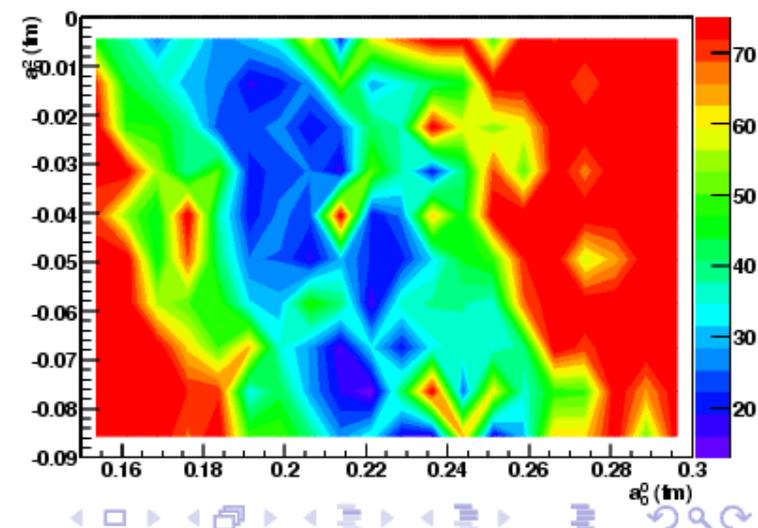

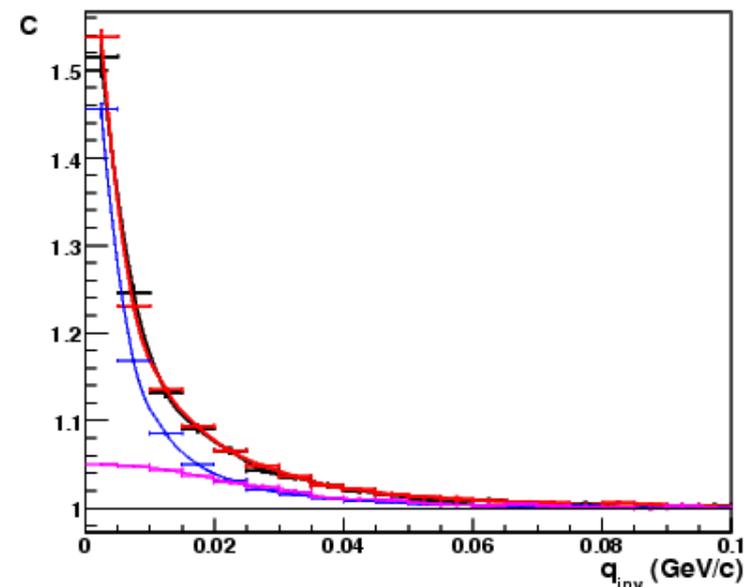

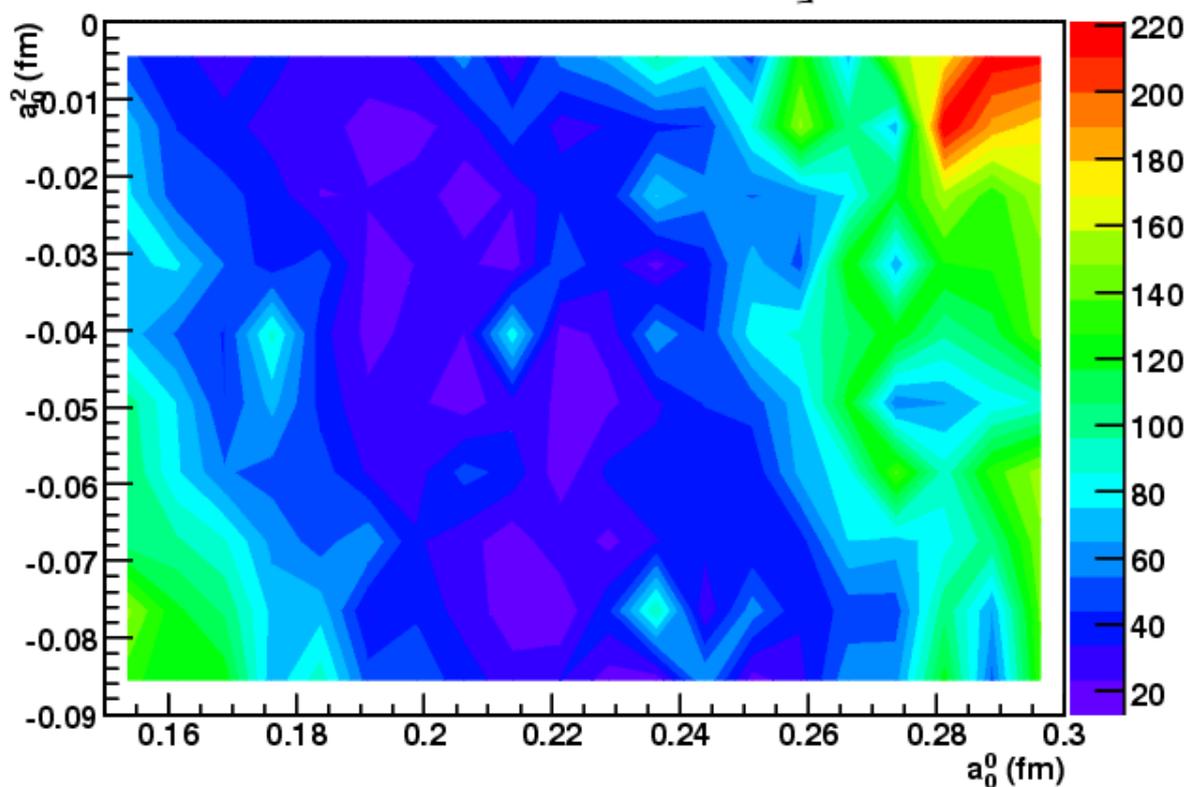

$$a_0^0 - a_0^2 = -0.265 \pm 0.004 [m_\pi^{-1}]$$

# Scattering length from STAR

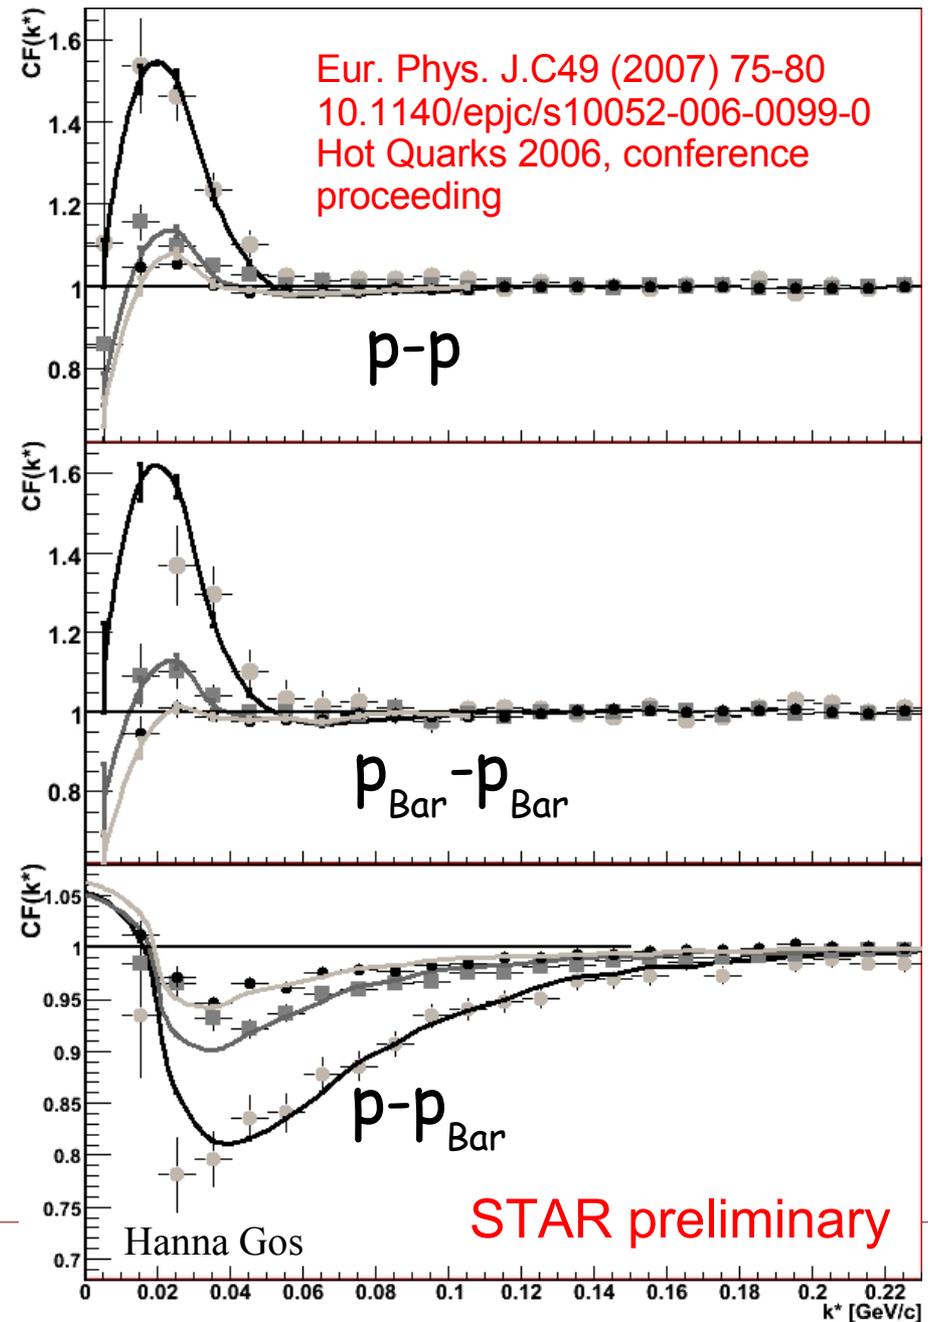

$k_T$ : 0.125–0.250 GeV/c

- ▶ PRELIMINARY results
- ▶ Coulomb + Strong FSI fit to data  $\longrightarrow$
- ▶ vary  $a_0^0, a_0^2 \implies \chi^2$  map

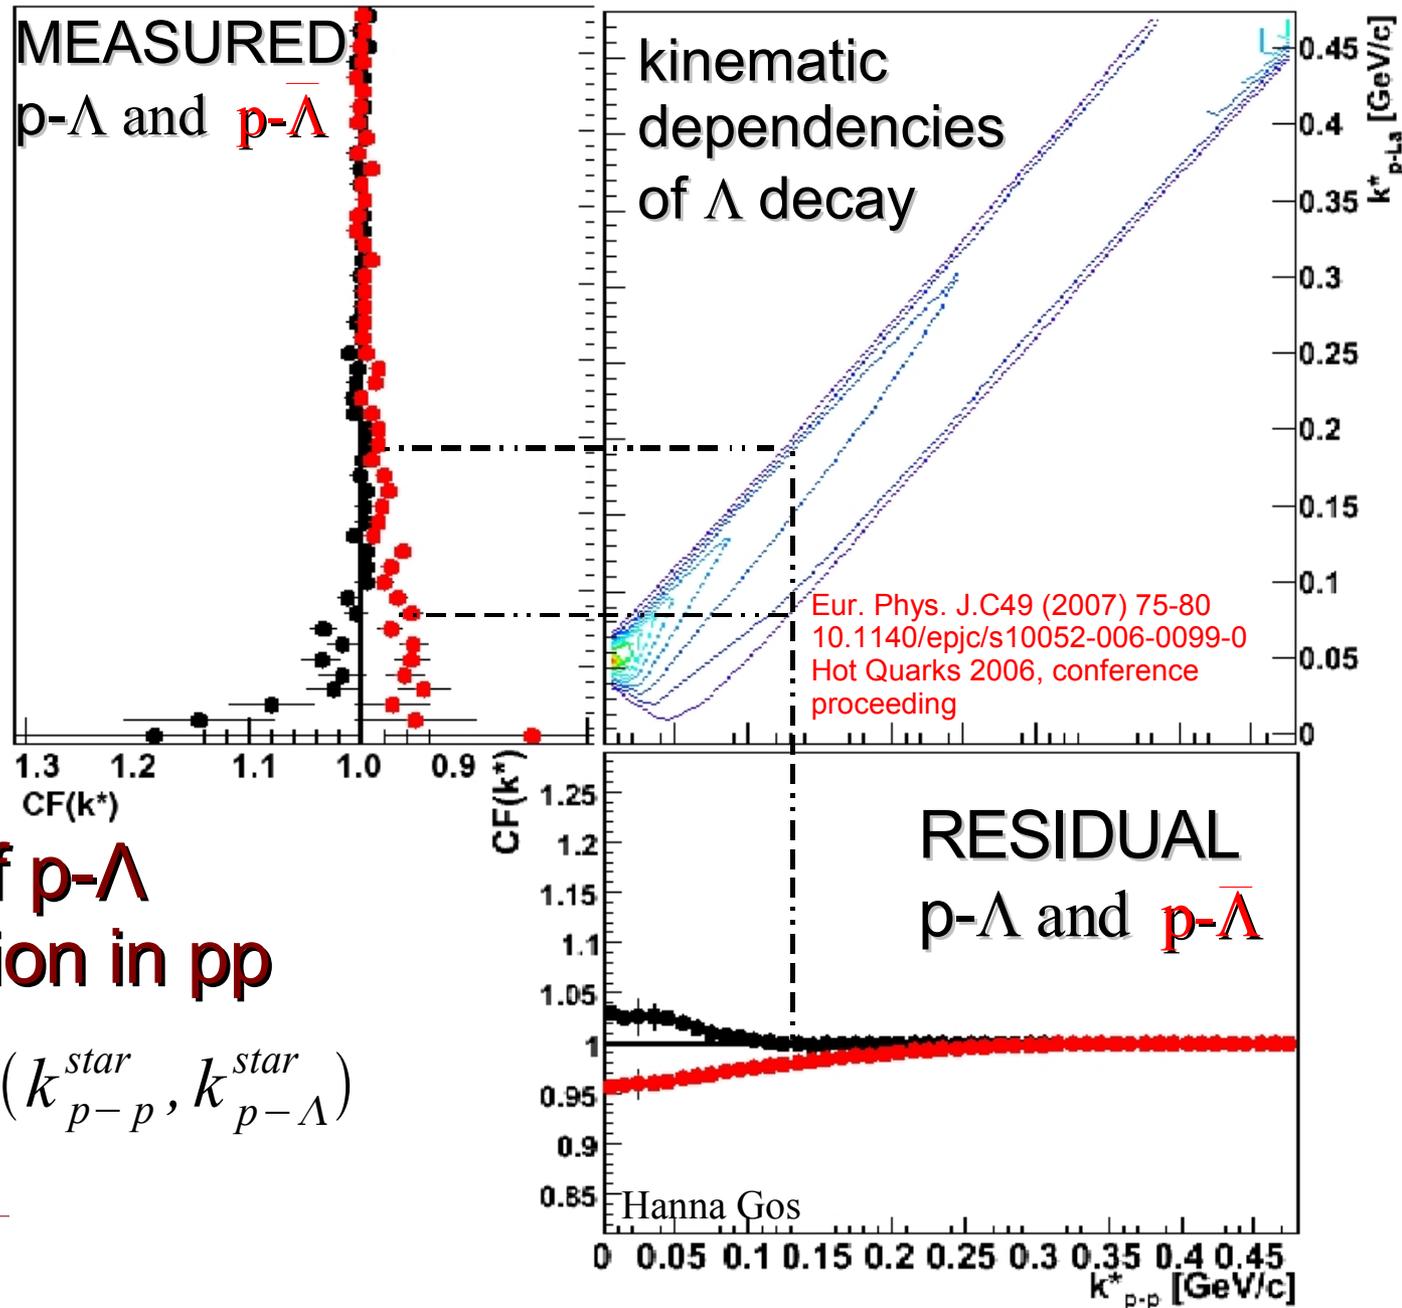

# Correlations with (anti-)baryons

- We want to test the scaling laws for particles with different properties (larger mass, baryons)
- The proton-antiproton correlation functions have been measured for the first time
- Simple purity correction is not sufficient for the baryon systems

# Residual correlations in pp system

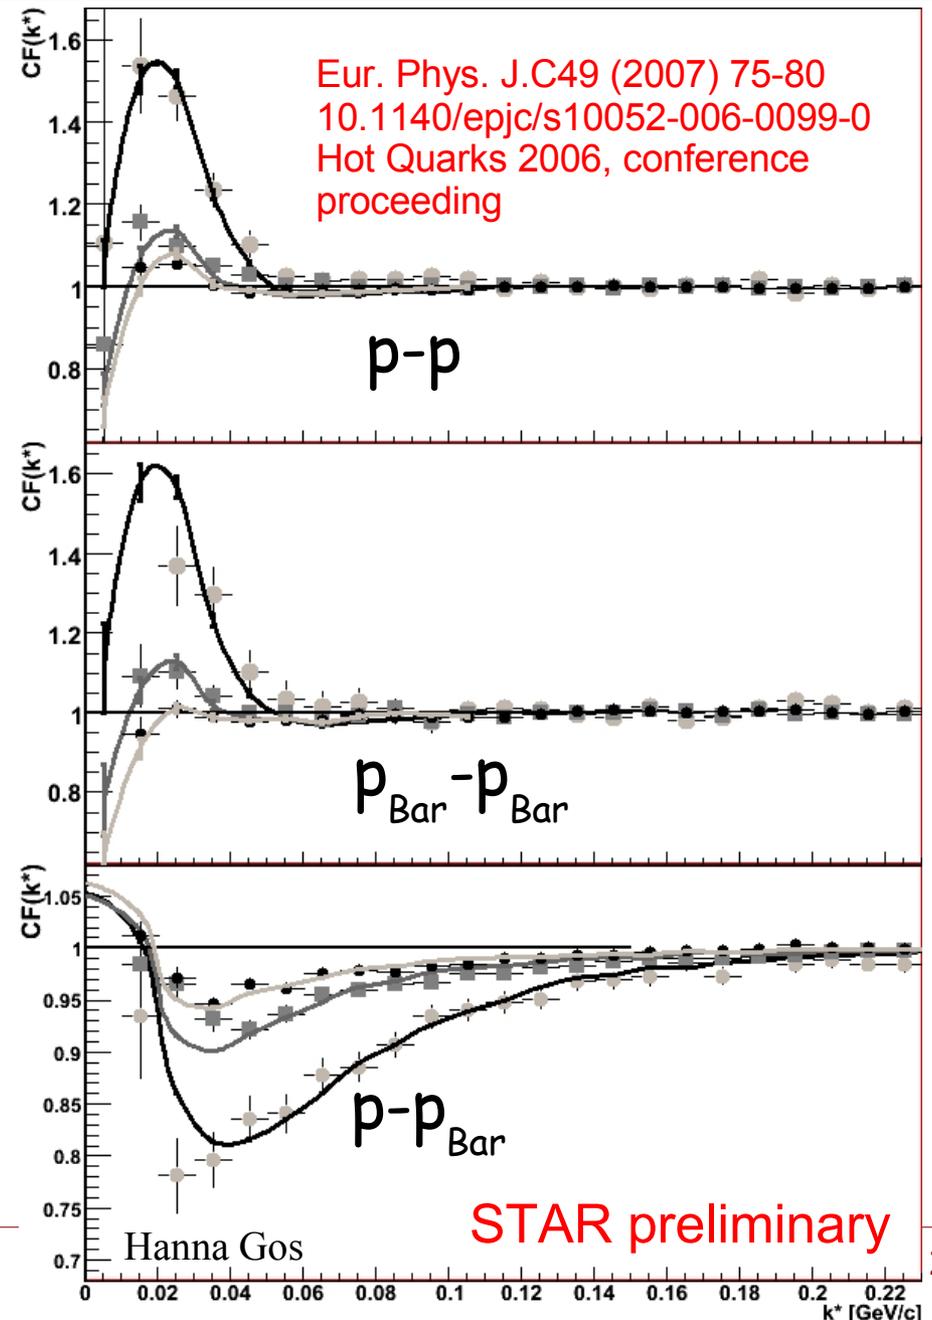

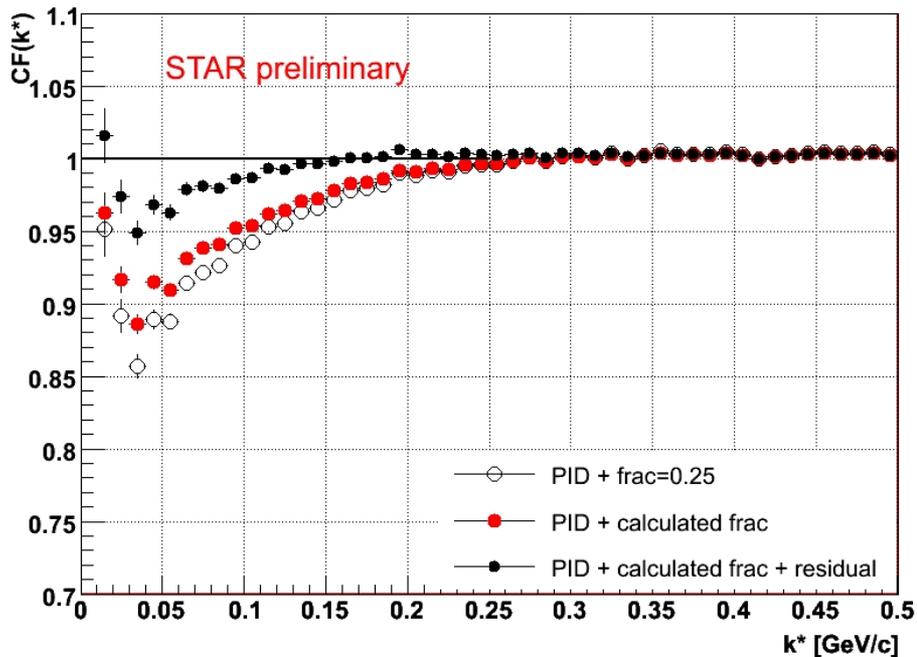

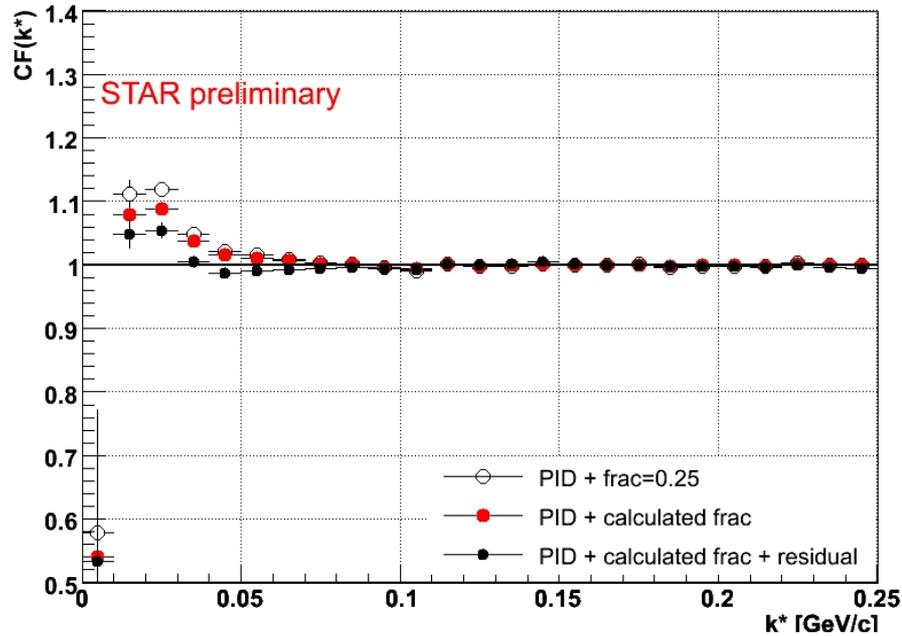

- Residual correlation of  $p\Lambda$  carries over to proton-(anti-)proton correlation

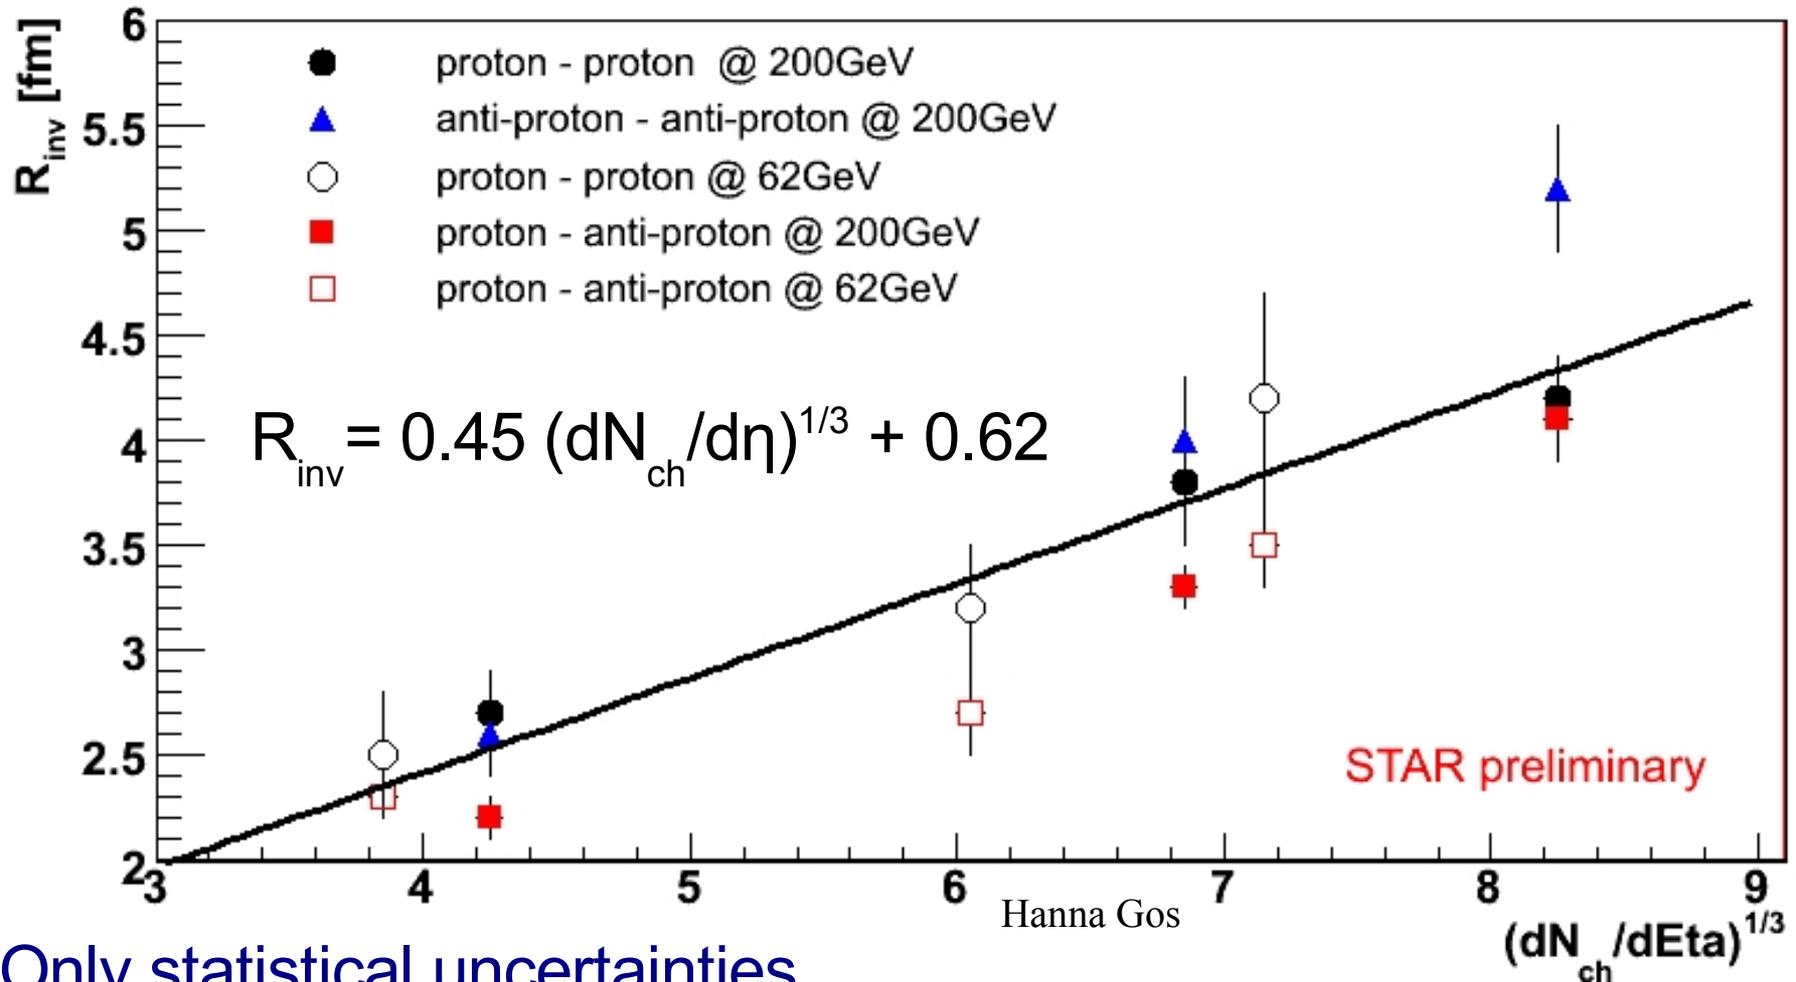

The estimation of  $p\Lambda$  residual correlation in pp

$$\sum_{k_{p-\Lambda}^{star}} CF_{p-\Lambda}^{meas}(k_{p-\Lambda}^{star}) W(k_{p-p}^{star}, k_{p-\Lambda}^{star})$$

# Results after residual corrections

# Multiplicity scaling for baryons

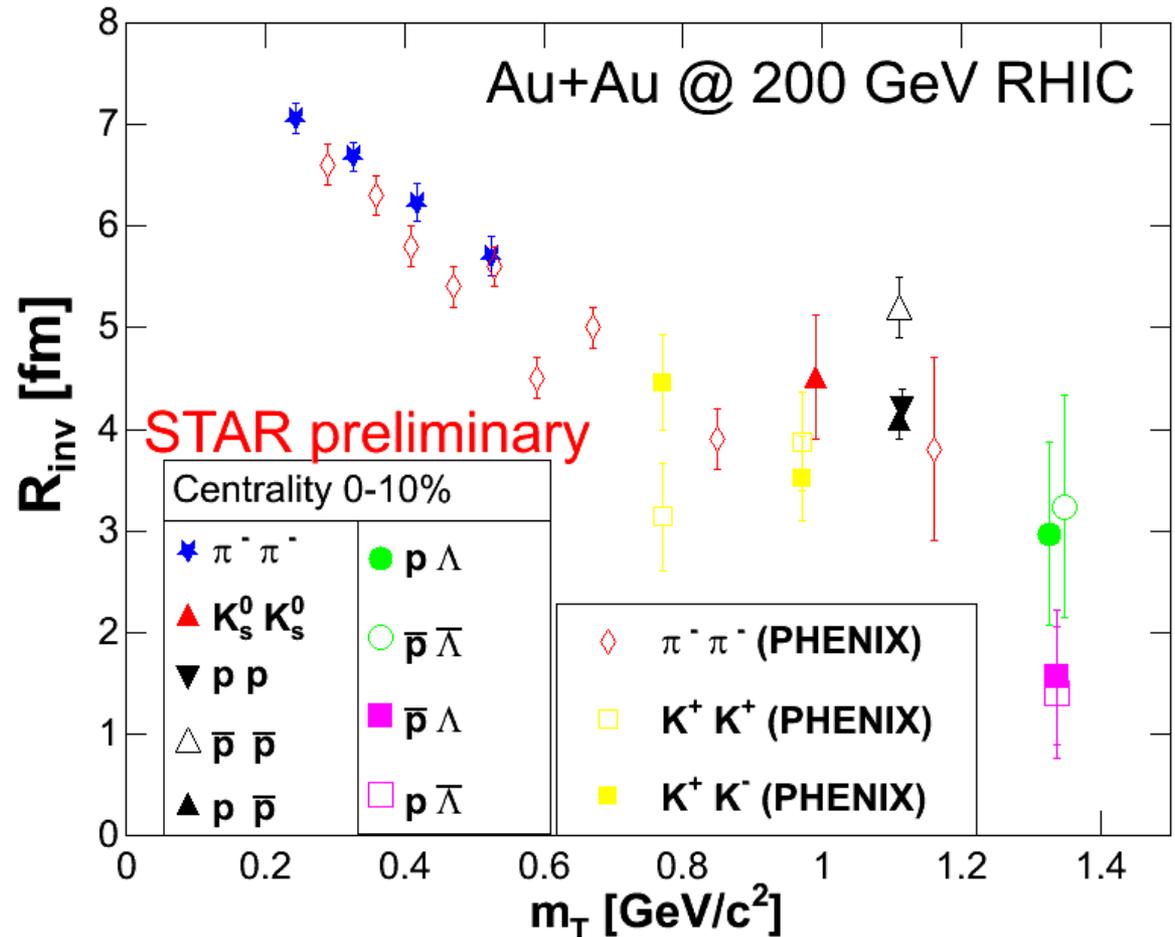

Only statistical uncertainties  
 Systematic error  $\sim 0.5$  fm not shown

Eur. Phys. J.C49 (2007) 75-80  
 10.1140/epjc/s10052-006-0099-0  
 Hot Quarks 2006, conference  
 proceeding

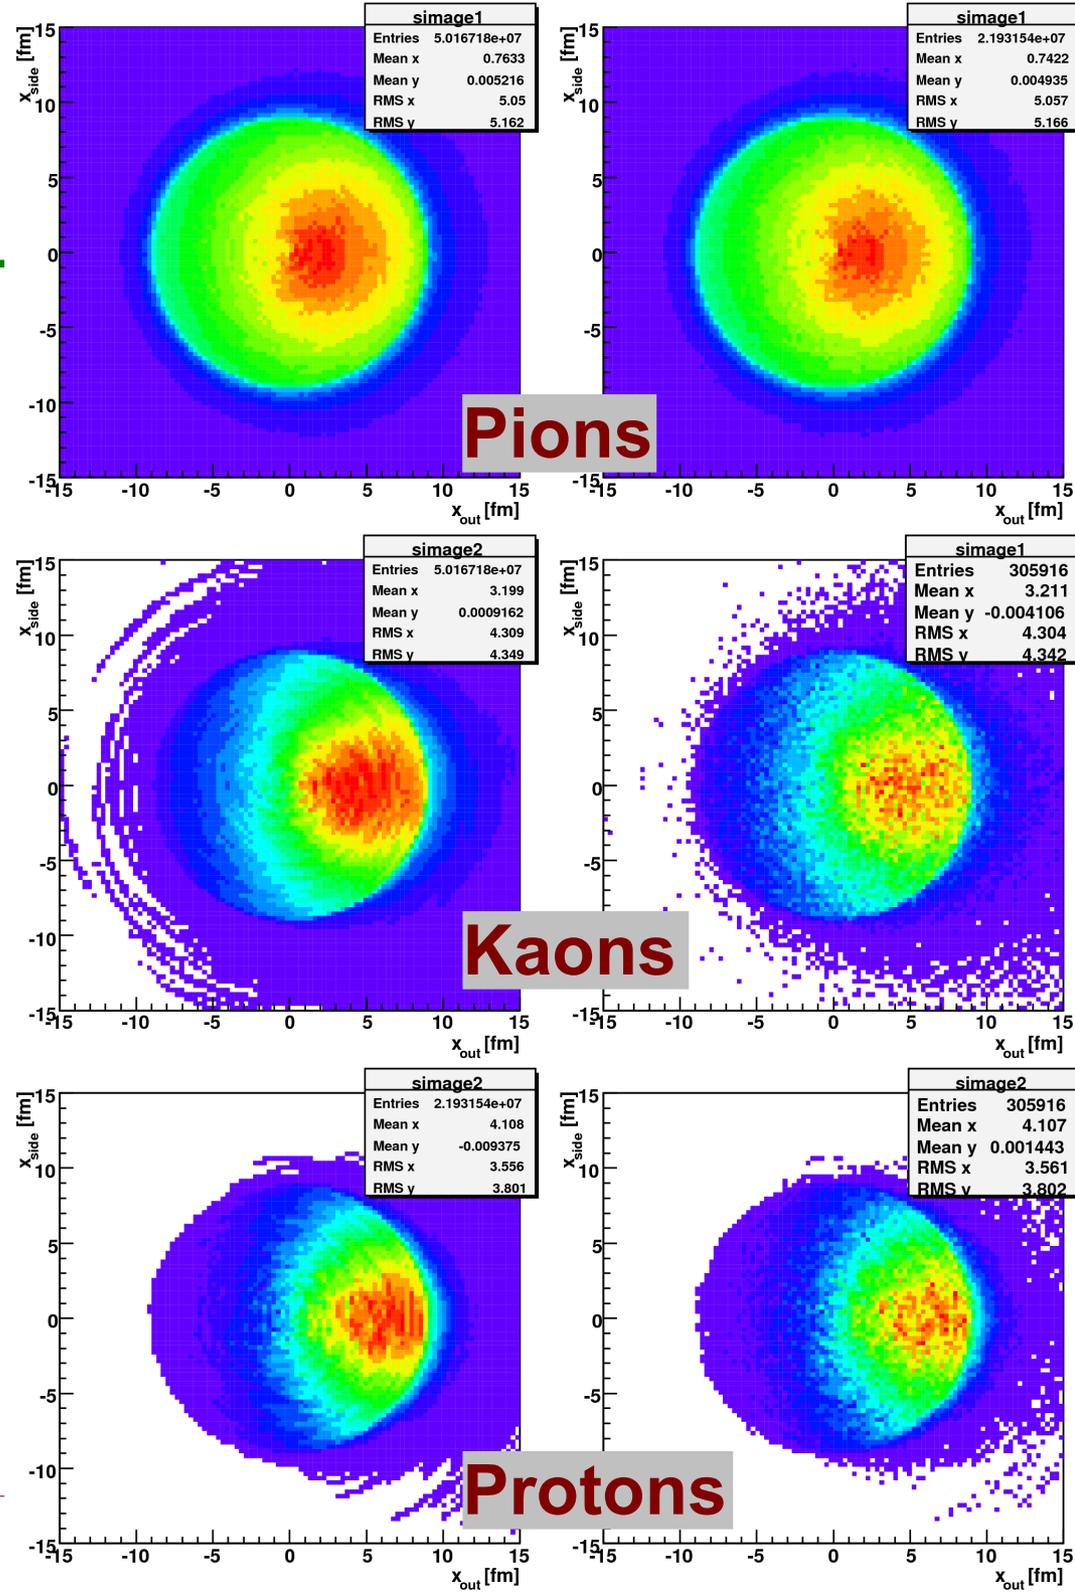

# Global $m_T$ dependence

- All particle species follow the global  $m_T$  systematics – building a consistent picture of collective dynamics

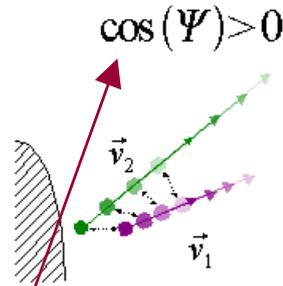

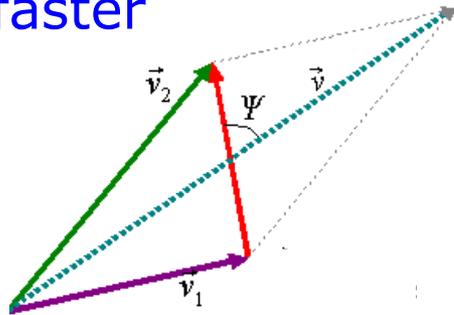

# Emission points and flow

- The effects of radial flow are two-fold:
  - The average emission points in *out* direction are different for pions, kaons and protons – spatial shift between particles of different masses
  - The average size of emission region gets smaller with particle mass –  $m_T$  scaling of radii

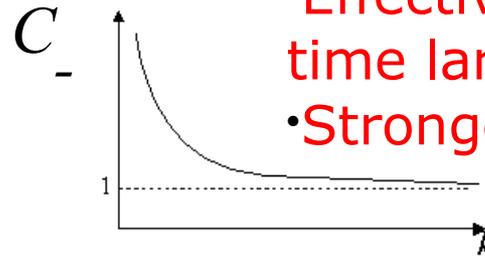

# The asymmetry analysis

Heavier particle faster

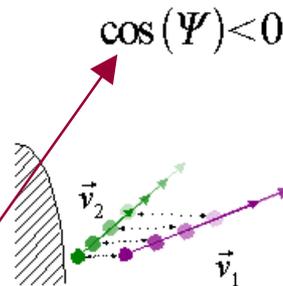

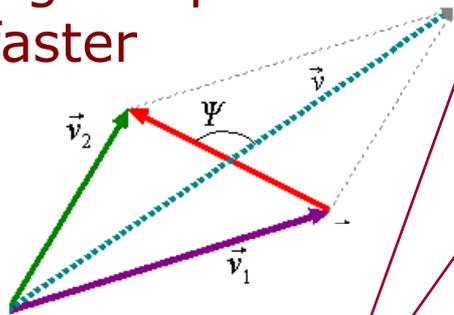

## Catching up

- Effective interaction time larger
- Stronger correlation

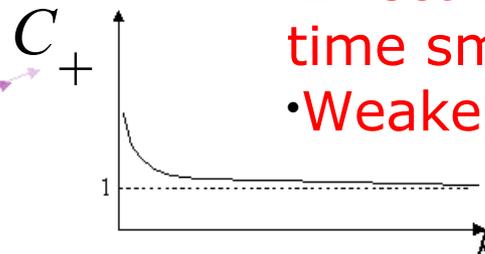

Lighter particle faster

## Moving away

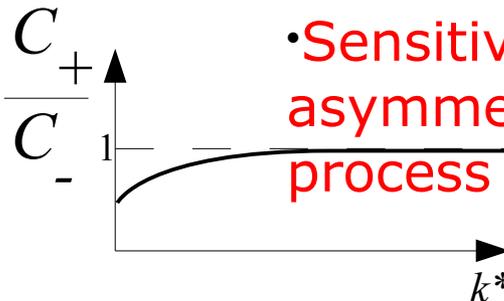

- Effective Interaction time smaller
- Weaker correlation

Kinematics selection along some direction  
e.g.  $k_{\text{Out}}$ ,  $k_{\text{Side}}$ ,  $\cos(v, k)$

## "Double" ratio

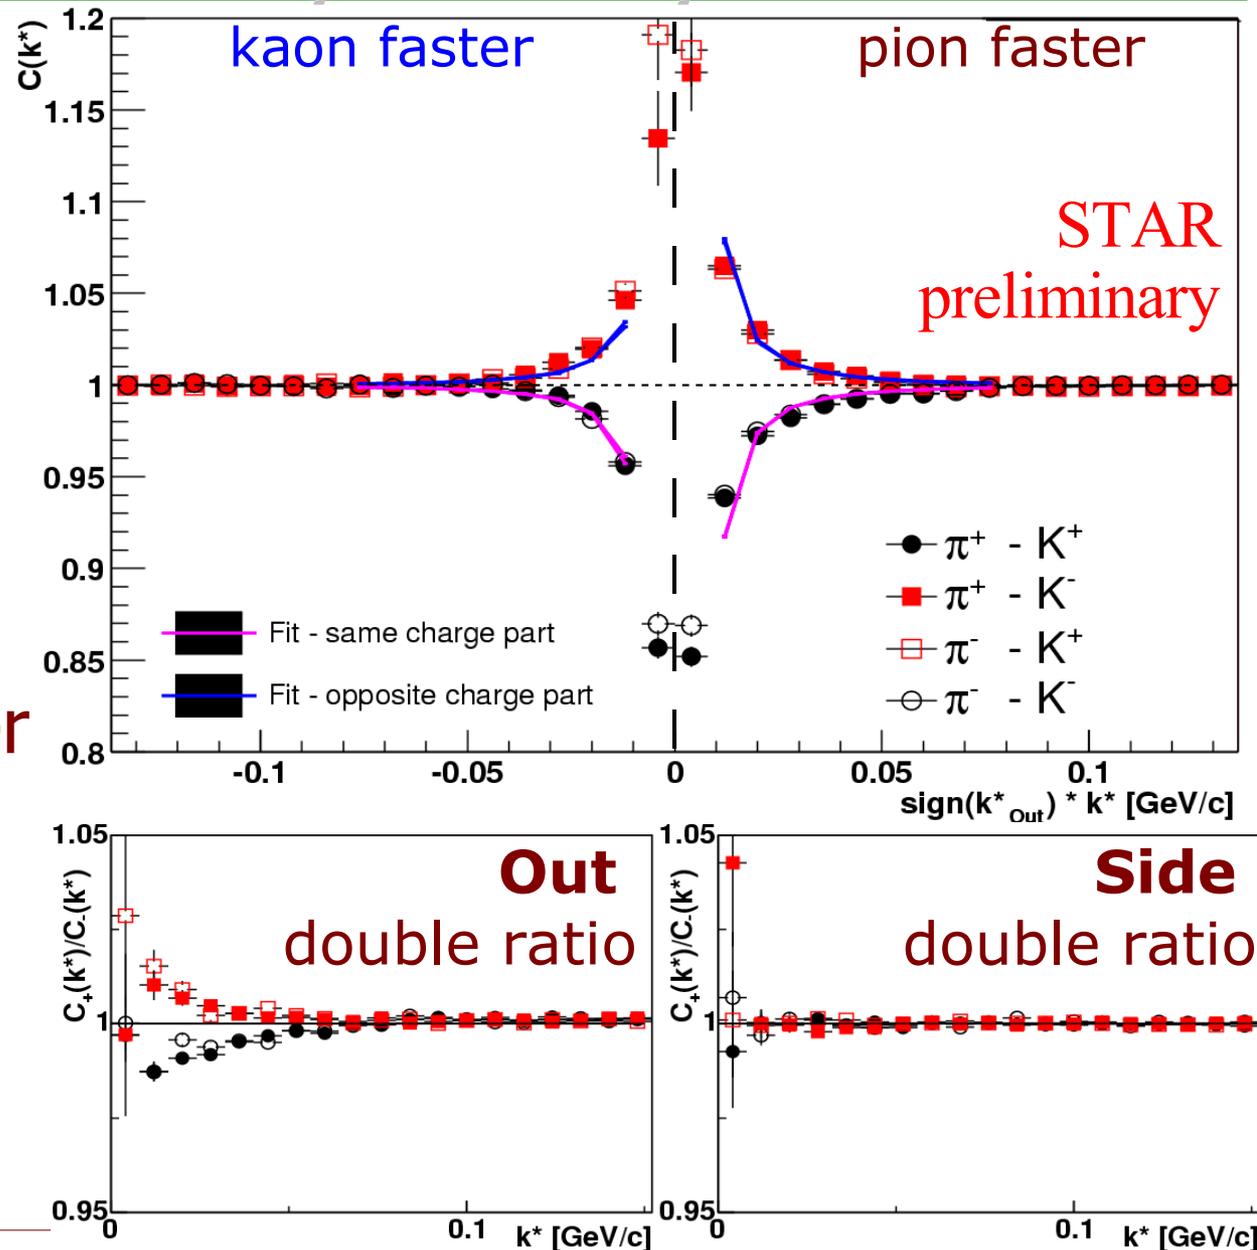

- Sensitive to the space-time asymmetry in the emission process

R.Lednicky, V. L.Lyuboshitz,  
B.Erazmus, D.Nouais,  
Phys.Lett. B373 (1996) 30.

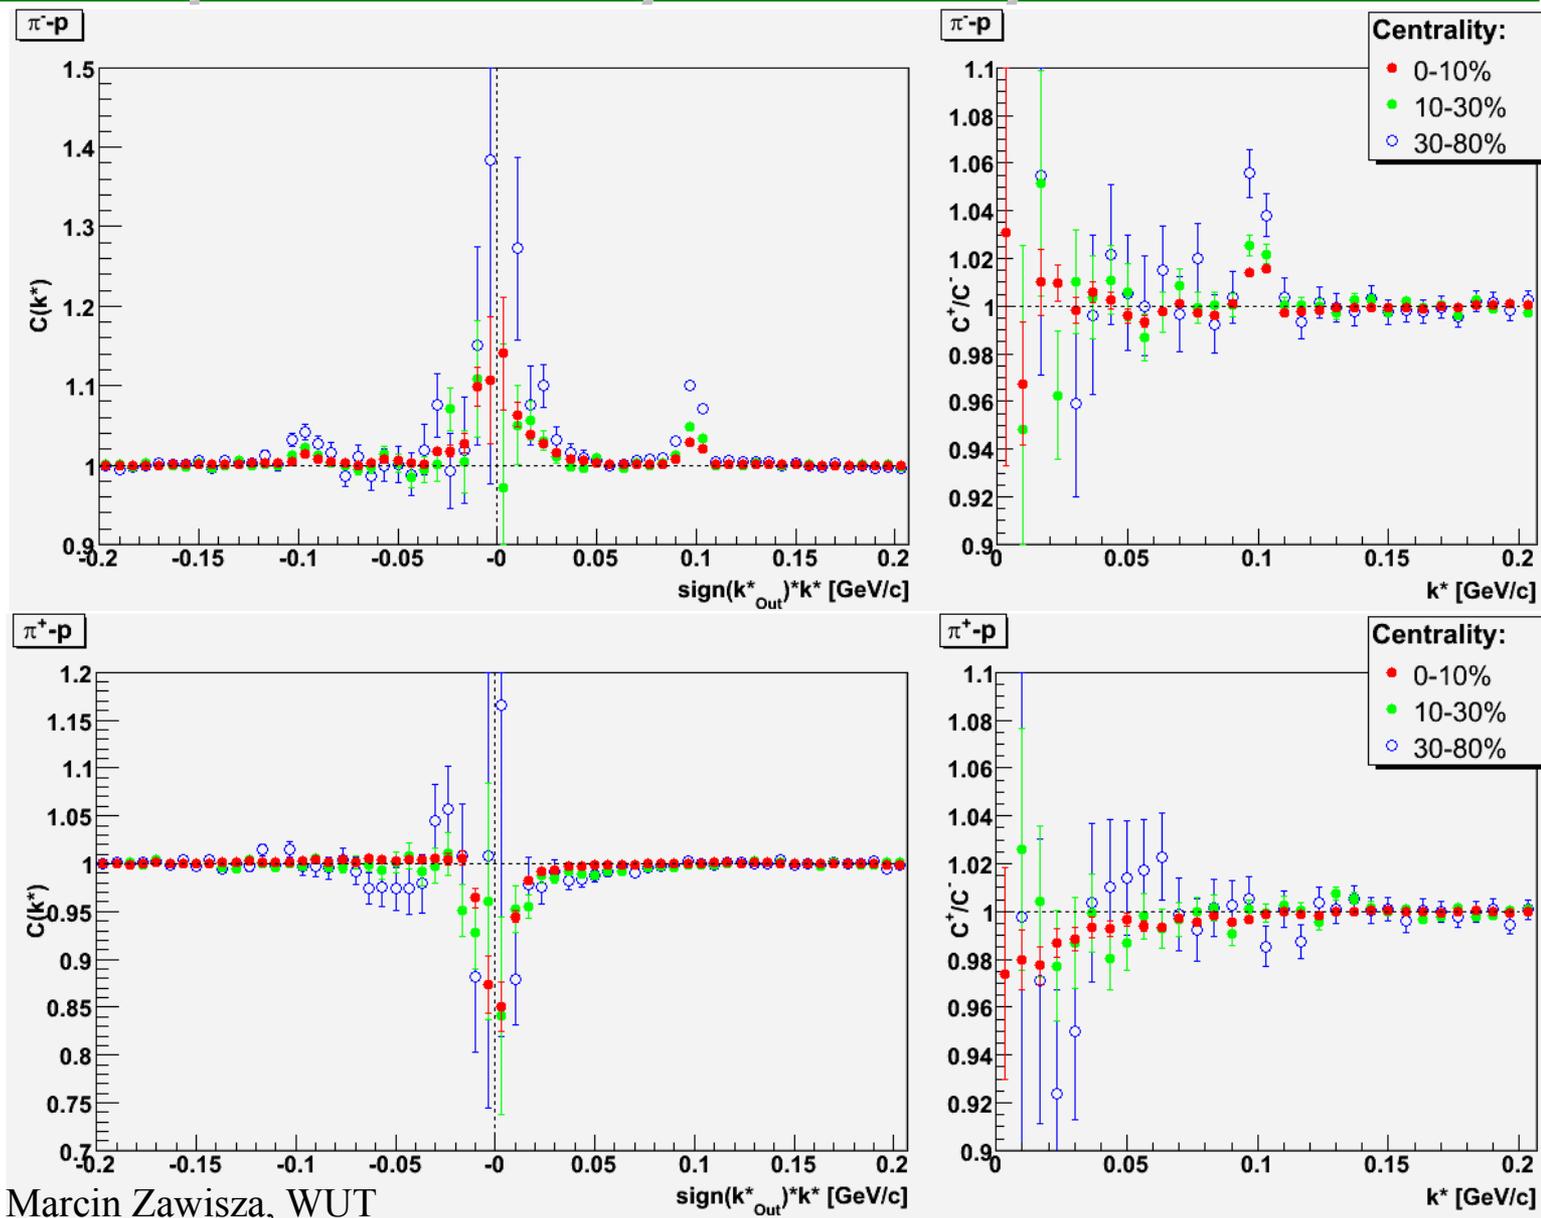

# Pion-Kaon asymmetry

- Good agreement for same-charge combinations
- Clear emission asymmetry signal
- Systematic error under study – influenced by purity and fits to all CFs separately

# Pion-proton asymmetry

- Asymmetry is observed for pion-proton systems, for all centralities, consistent with the radial flow hypothesis

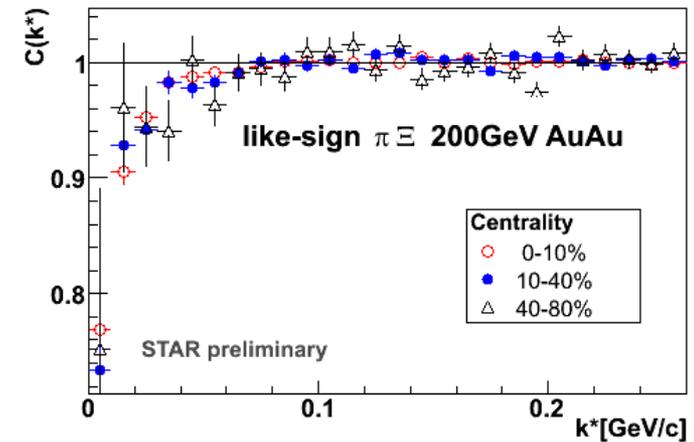

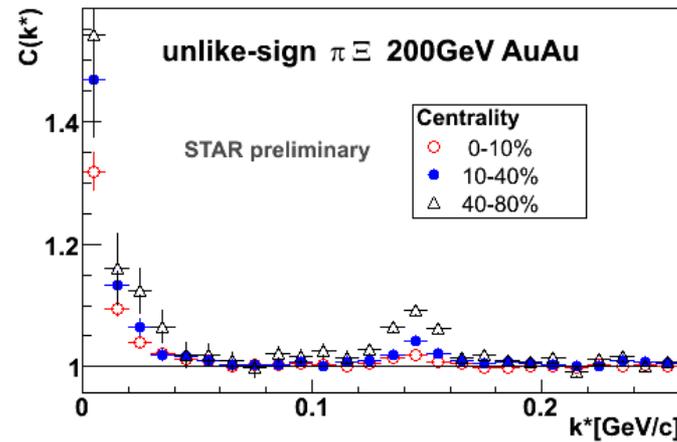

# Why $\pi$ - $\Xi$ correlations?

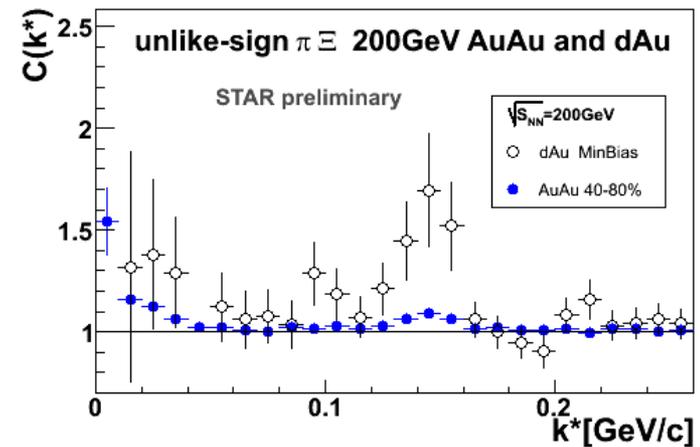

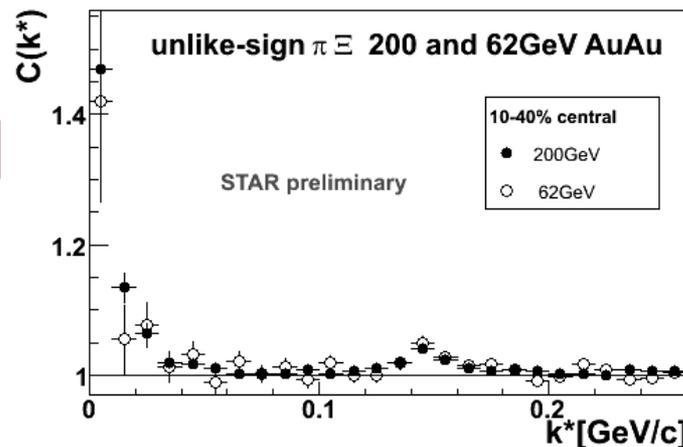

- Why is  $\Xi$  elliptic flow comparable to other hadrons? Is that all suggesting early partonic collectivity?
- $\Xi$  (as well as other multi strange baryons) may have thermal freeze-out behaviour differing from the other hadrons: early decoupling?
- What is the production mechanism of  $\Xi^*(1530)$  resonance?

# Femtoscscopy with exotic systems

- Robust signal is seen for pion-Xi correlations in both like-sign and opposite-sign systems.

- Significant  $\Xi^*$  peak is observed as well as the correlation coming from Coulomb

Petr Chaloupka

# Fitting the emission asymmetry

Petr Chaloupka

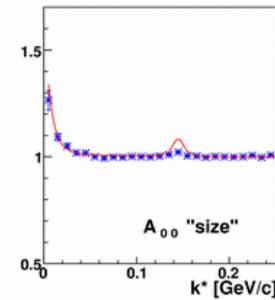

- Emission asymmetry is observer for all pair types confirming strong radial flow of Xi
- Size suggests early Xi freeze-out
- Asymmetry seems to divide pairs into baryon and anti-baryon groups

$\pi^- \Xi^+$

$\sigma = 6.75 \pm 1.28 \text{ fm}$

$\langle \Delta r_{\text{out}}^* \rangle = 3.75 \pm 2.99 \text{ fm}$

$\chi^2 / \text{NDF} = 158 / 149 = 1.064$

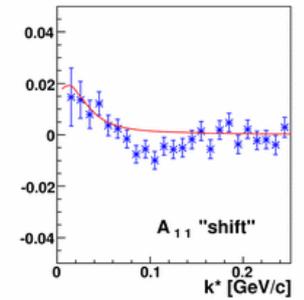

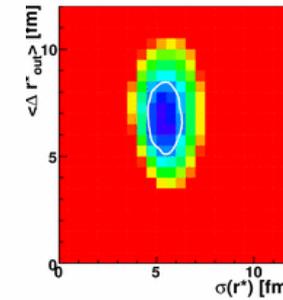

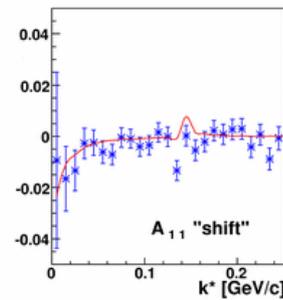

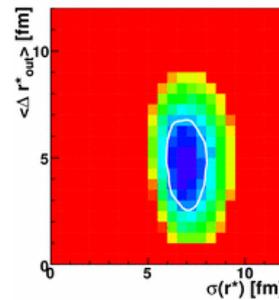

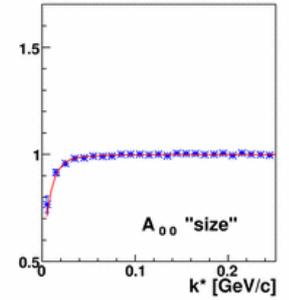

$\pi^- \Xi^-$

$\sigma = 5.25 \pm 1.05 \text{ fm}$

$\langle \Delta r_{\text{out}}^* \rangle = 7.25 \pm 2.04 \text{ fm}$

$\chi^2 / \text{NDF} = 166 / 149 = 1.118$

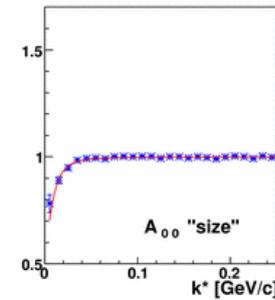

$\pi^+ \Xi^+$

$\sigma = 5.75 \pm 1.03 \text{ fm}$

$\langle \Delta r_{\text{out}}^* \rangle = 2.75 \pm 1.92 \text{ fm}$

$\chi^2 / \text{NDF} = 157 / 149 = 1.054$

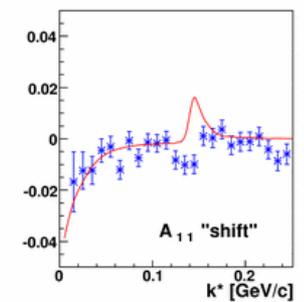

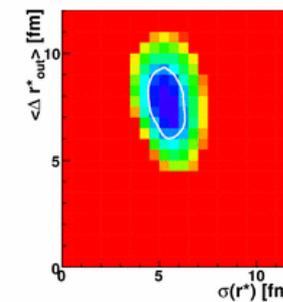

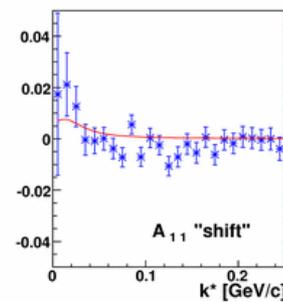

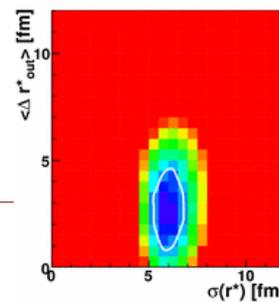

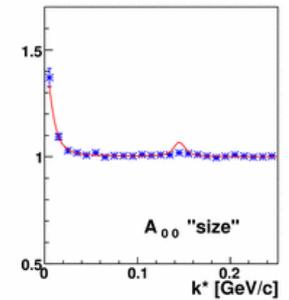

$\pi^+ \Xi^-$

$\sigma = 5.25 \pm 1.05 \text{ fm}$

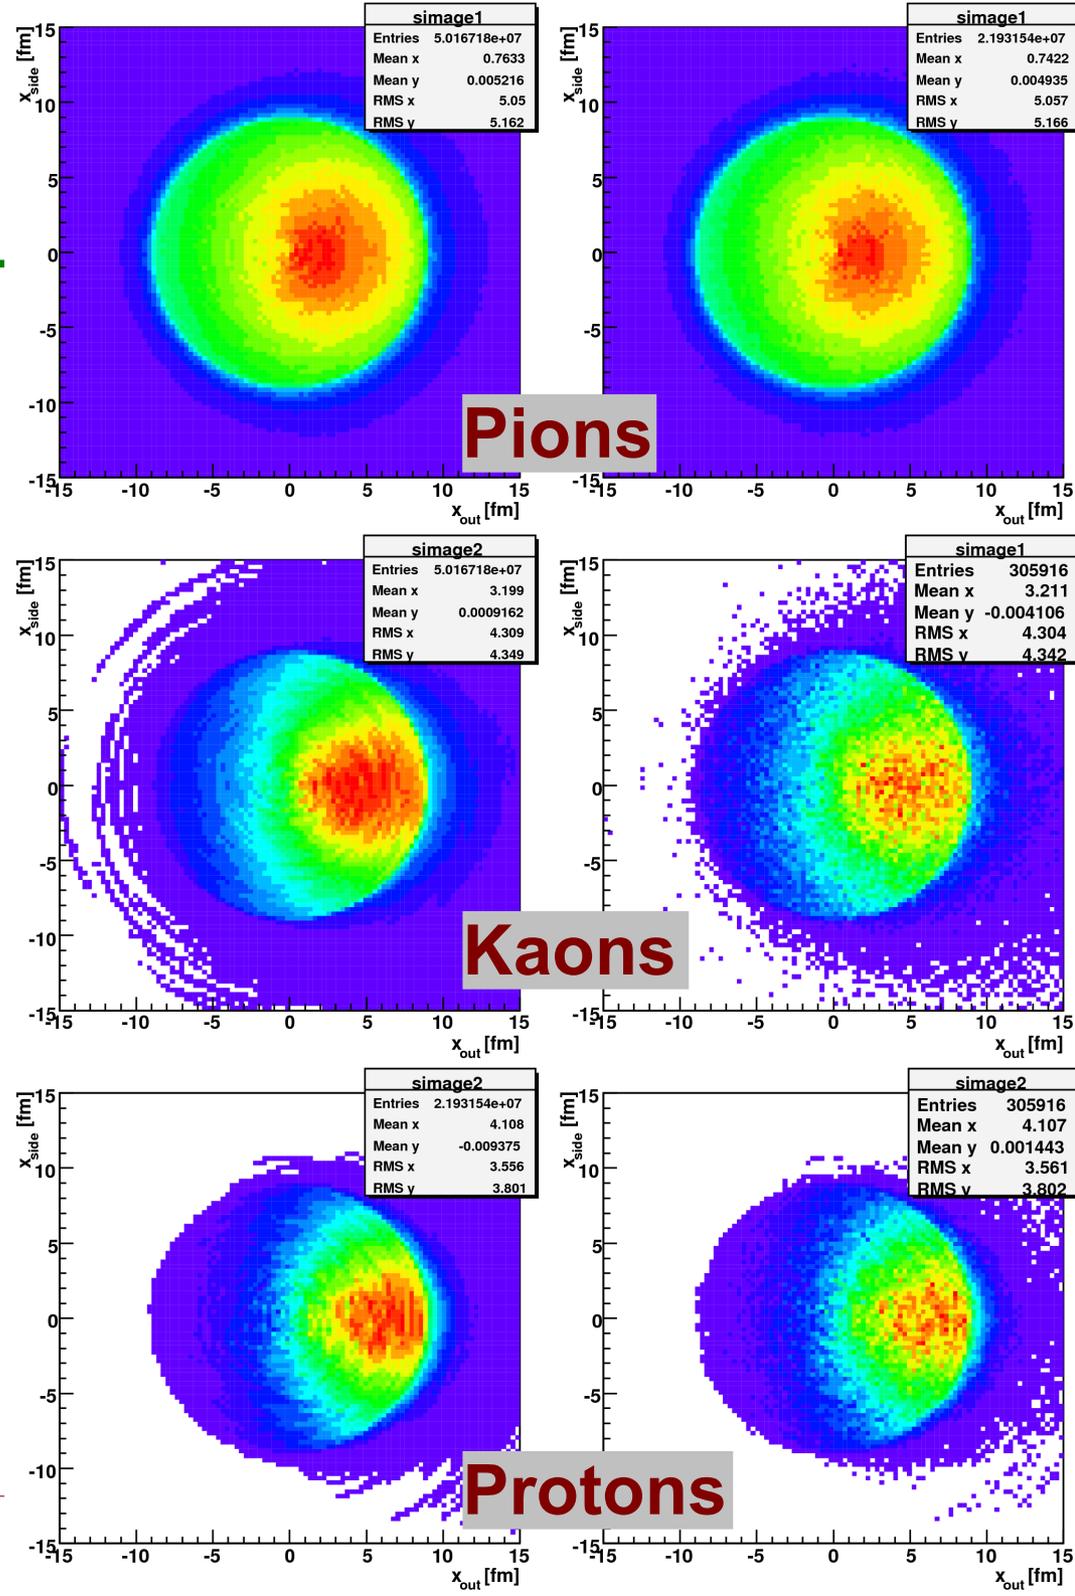

$\langle \Delta r_{\text{out}}^* \rangle = 7.75 \pm 1.68 \text{ fm}$

$\chi^2 / \text{NDF} = 131 / 149 = 0.880$

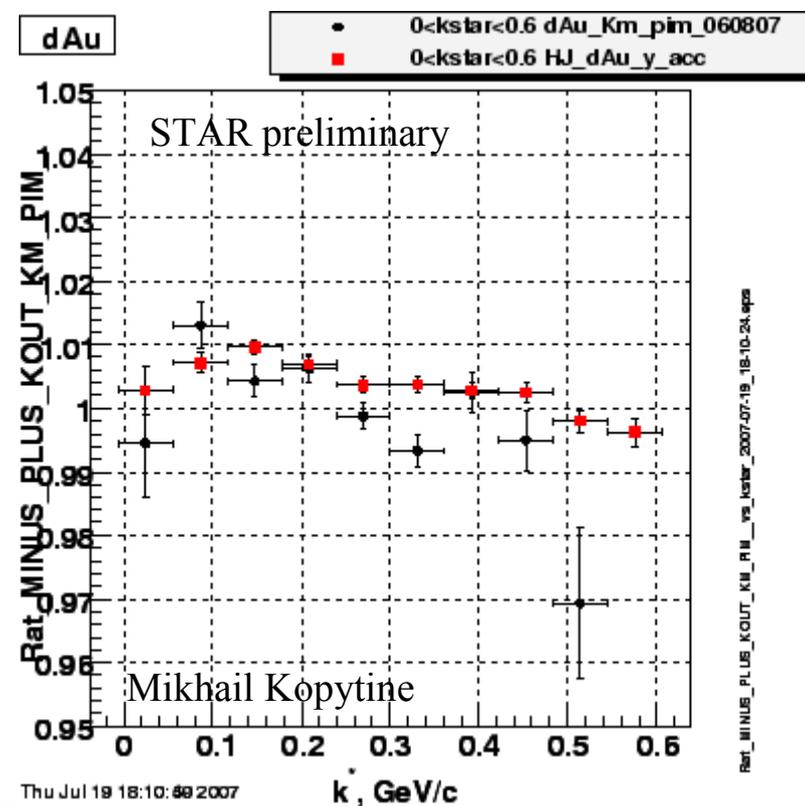

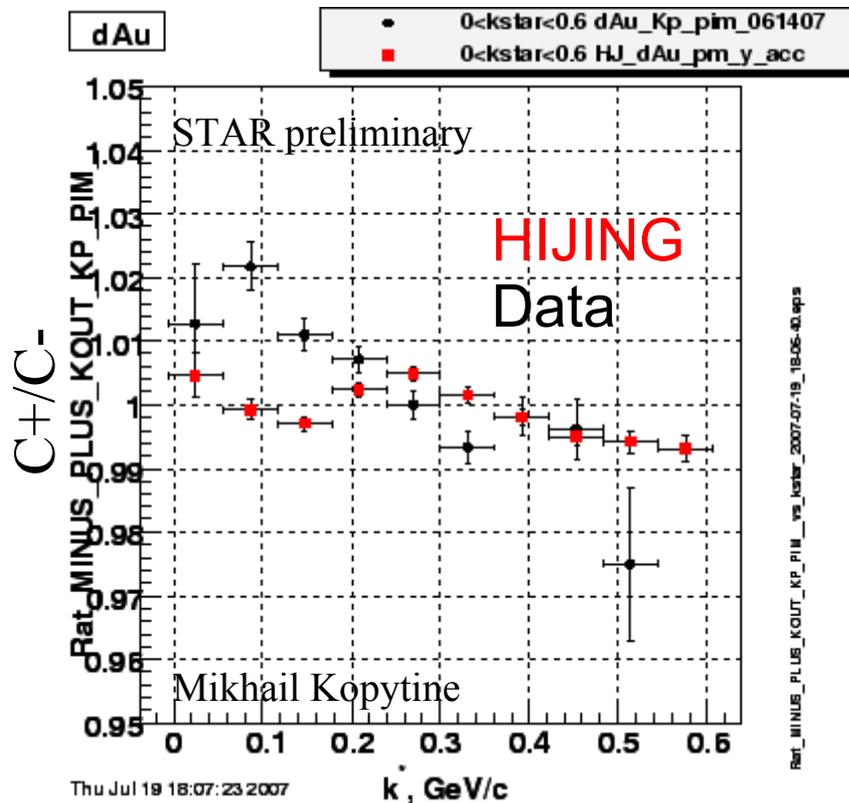

# Emission points and flow

- The effects of radial flow are two-fold:
  - The average emission points in *out* direction are different for pions, kaons and protons – spatial shift between particles of different masses
  - The average size of emission region gets smaller with particle mass –  $m_T$  scaling of radii

# Asymmetry in dAu

- Long-range structure observed – reproduced by HIJING simulations
- Femtoscopic asymmetry signal seems to remain at low  $k^*$

# Summary

---

- STAR is continuing its femtosopic program both by pursuing well-established analyses for available energies and colliding types as well as by trying out new techniques and challenging measurements
- Traditional pion femtoscopy provides a consistent picture of collision geometry at RHIC
- An imaging technique promises to provide a detailed information about emission function
- Long-range baseline study has been performed for low-multiplicity collisions
- Asymmetry measurements provide unique information about space-momentum structure of the emission
