Studying Neutrinos with FINeSSE

- Neutrinos in the Standard Model
- Using neutrinos to probe nuclear structure
- Neutrino cross sections
- Measurements with FINeSSE

Neutrinos are great probes because they are so simple!

Standard Model

12 elementary particles and how they interact

“no mass, no charge, no problem”

“Conventional” neutrino scattering is back in vogue

Past neutrino experiments
relatively low energy, low statistics
bubble chamber experiments

Moved to higher energy
experiments
higher rates
new physics

Rekindled interest in
neutrino interaction physics
at low energies

- high flux neutrino sources
- higher precision detectors

within the last decades,
neutrino oscillation physics
lots of interest
moved back to lower energies

Rekindled interest: Entering the era of precision neutrino physics

Lots of data pouring out of these experiments and lots of older data used for development of cross section monte carlos

NuINT workshops established

Durham data base project has pulled all this together!
(Zeller, Whalley, Gallagher, Hawker, Sakuda)

Different cross section monte carlos from different experiments in similiary energy ranges

- comparisons teach us about underlying models.

NUANCE (MiniBooNE)

NEUGEN (MINOS)

NEUT (K2K)

Rich energy region: different channels turning on and off

A lot going on at low energies:

↓
quasi-elastic
single π
(DIS turning on)

clean beams,
but flux and
cross sections
dropping rapidly
need intense beams!

Significant overlap with
accelerator neutrino
oscillation searches

- important for oscillation physics
- parasitic beam usage

FINeSSE

Fine-grained Neutrino Scattering Experiment

- Measure strange spin of proton
- Measure a suite of low energy cross sections

Strange Spin of Nucleon

(Δ_s : the strange quark contribution to the nucleon spin)

This will address a fundamental aspect of nucleon structure:

- What carries the nucleon spin! valence quarks, sea quarks, gluons?
- Can we describe the proton in terms of a fundamental theory?

RHIC spin will tell us a lot, but not Δ_s ...

Low energy neutrino scattering is a great way to probe the strange spin of the proton

Who has already measured Δs ?

Polarized-lepton DIS
(EMC, SMC, SLAC)
extract the quark contributions
to the spin of the nucleon via
the axial structure function

$$g_1(x, Q^2)$$

strange contribution

$$\Delta s \sim -0.10 \pm 0.05$$

- dependent on assumptions of SU(3) flavor symmetry
- worry about extrapolation to $x=0$

Results from HERMES

Semi-inclusive scattering: tag p , k , or π in coincidence with outgoing charged leptons.
Flavor tags different quark distributions....

PRL **92**, 012005 ('04).

$$“\Delta s” = 0.03 \pm 0.03 \pm 0.01 \quad (0.023 < x < 0.30)$$

- Is fragmentation understood?
Does this agree with inclusive result?

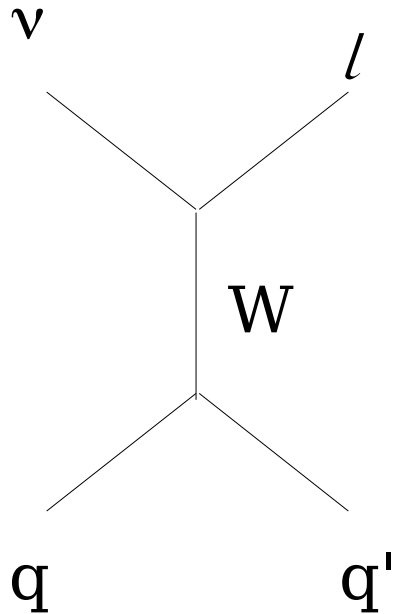

Measurement via neutrino-nucleon
elastic-scattering to determine Δs directly

This method requires:

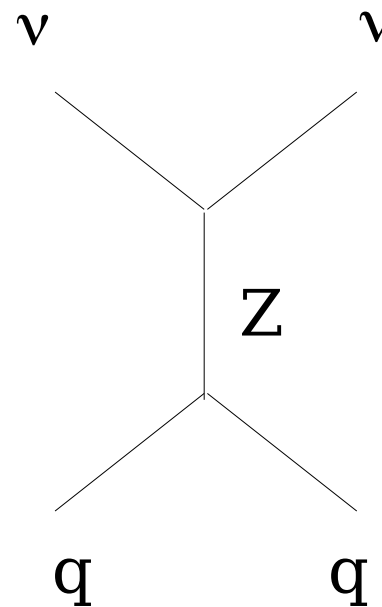

- no extrapolation to $x=0$
- no assumptions of SU(3) symmetry

A theoretically robust measurement of Δs

Measuring Δs using neutrinos

quasi-elastic CC
scattering
 q =up and down
quarks only

Neutral current scattering
 q =any quark in the nucleon
-> strange quarks

$\nu N \rightarrow \nu N$ scattering and Δs

- Nucleon Neutral Weak Current depends on:

$$\langle f | J_\mu^H | i \rangle = \bar{u}_f(p') \left[\gamma_\mu F_1(Q^2) + i \frac{\sigma^{\mu\nu} q_\nu F_2(Q^2)}{2M_p} + \gamma_\mu \gamma_5 G_A(Q^2) \right] u_i(p)$$

extract axial form factor, G_A
(get F_1, F_2 from other expts)

- $G_A(Q^2) = -\tau_z g_A(Q^2) + G_A^s(Q^2)$
 - g_A known (nuclear β decay)
 - $G_A^s(Q^2=0) = \Delta s$

Measure $\nu p \rightarrow \nu p$ at low Q^2

NC neutrino scattering: BNL E734

The best measurement of νN NC scattering to date is from BNL E734:

- $\nu p, \bar{\nu} p$ elastic scattering,
- w/170 ton segmented detector,
- @ $E_{\nu} \sim 1.2$ GeV ,
- $Q^2 = 0.45$ to 1.05 GeV²
- Ahrens et al., PRD 35, 785, '87.

BNL734 (PRD 35, 785, '87):

BNL734 detector

NC neutrino scattering: BNL E734

- A fit to the νp , $\bar{\nu} p$ elastic scattering diff xsection yielded: $\Delta s = -0.15 \pm 0.09$
(Ahrens et al., PRD 35, 785, '87.)

- This data has generated much interest...
and several reanalyses:

- (Garvey et al., PRC48, 761, 1993): more realistic values for vector form factors, Q^2 evolution $\rightarrow \Delta s = -0.21 \pm 0.10 \pm 0.10$

- (Alberico et al., Nucl. Phys. A651, 277, 1999), considered ratios of NC,CC cross sections $\rightarrow \Delta s$ consistent with above

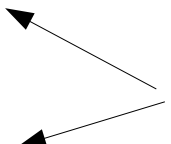

- (Pate, PRL 92, 082002, '04): combines E734 data with eN data from HAPPEX, yields $G_A^s(Q^2=0.5 \text{ GeV}^2)$, but data not close enough to $Q^2=0 \rightarrow$ no Δs extraction.

- The BNL734 data is not accurate enough
to address the DIS measurements

systematic and statistical errors are too large

Ingredients for precision, low energy, neutrino scattering measurements

- High intensity beams -> high event rates statistical errors
- Minimize flux uncertainties
 - 15-20% in the past -> 5% expected by MiniBooNE and MINOS systematic errors
- Minimize background contamination
 - low energy neutrino spectrum (below DIS turn-on and with small high energy tail)
 - fine-grained detector -> good final state separation

High Statistics

The Right Flux

“Low” energy neutrino
beam produced
from 8 GeV POT
on target

Excellent ν energy distribution
for the Δ_s measurement

- High enough...
 - large elastic cross section
 - minimize nuclear effects
- and Low enough to minimize backgrounds (DIS) small
- little to no high-energy "tail"
- Low Duty Factor also => very small cosmic background

Minimize flux error further:
Take advantage of cross section ratios!

→ Ratio of neutral-current elastic scattering on protons to neutrons*:

$$R(p/n) = (\nu p \rightarrow \nu p) / (\nu n \rightarrow \nu n)$$

is quite sensitive to $G_A^s(\Delta s)$ because:

$$G_A = -g_A \tau_z + G_A^s, \quad (\tau_z = 1 \text{ p}, -1 \text{ n})$$

However, the systematic errors of neutron detection are problematic. So...

Ratio of NC elastic scattering to CC quasi-elastic scattering:

$$\rightarrow R(\text{NC}/\text{CC}) = (\nu p, \text{NC}) / (\nu p, \text{CC})$$

is somewhat less sensitive to Δs , **but experimentally easier.**

Very small systematic error due to the uncertainty in neutrino flux!

*(Garvey et al., PR C48, 1919, '93)

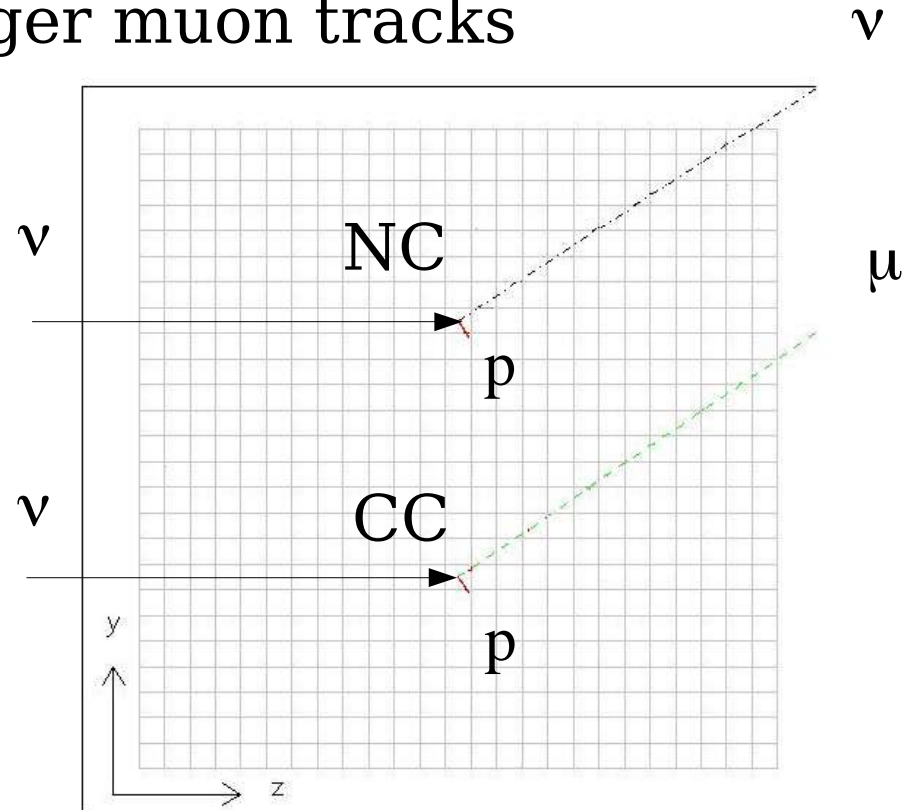

Fine-Grained Detector

Measures both short proton tracks
and longer muon tracks

-proton energy
measurement
down to $T_p \sim 100\text{MeV}$
($R \sim 10\text{cm}$)

-range out up to
1 GeV muons

- particle ID for
NC/CC/background
separation

GEANT-generated events in scintillator:
 $Q^2 = 0.2 \text{ GeV}^2$, $E_n = 800\text{MeV}$
 $T_p \sim 100 \text{ MeV}$, $T_m \sim 600 \text{ MeV}$

→ Two part detector

The Vertex Detector...

- to precisely track low-energy protons

The Muon Rangestack...

- to track and measure the energy of muons

neutrinos

Bartoszek Engineering

Vertex Detector: a large, low-threshold, 3D, tracking detector

Vertex Detector side view:

$(2.5\text{m})^3$ active liquid scintillator volume
- 19200 (80x80x3) 1.5 mm WLS fibers on 3cm spacing with 3 orientations

PMTs + on-board electronics

Considered a few different detector technologies for FINeSE.....

Scintillator stack

- optically isolated scintillator bars with wave length shifting fibers in each bar
- ie: K2K Scibar detector
MINOs/MINERvA detectors

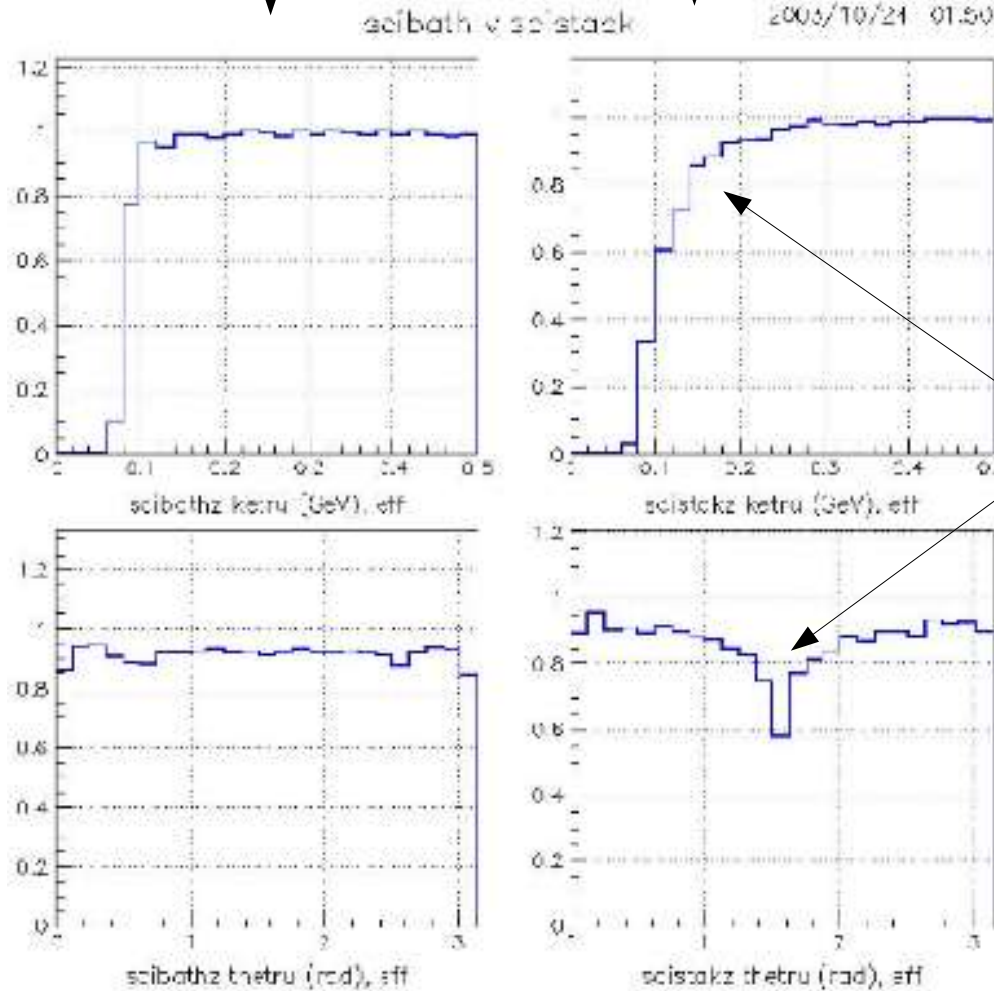

- not optically isolated
- information in 3D

Scintillator bath

Scibath

Plastic scintillator
stack

Lose
events at
high angles/low KE
in scintillator bar
type detector
compared to
Scibath

Prototype "Scibath" detector built to test technology:

- 30cm x 16 cm x 16 cm box
- filled with scintillator oil
- 6x5 array of 1.5mm multi-clad WLS fiber
- readout via 16 anode MAPMT

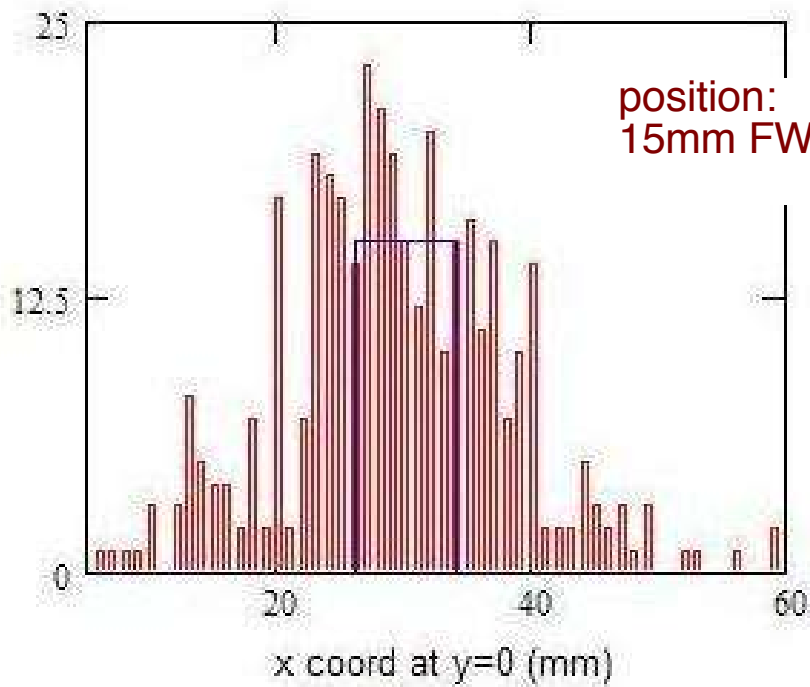

tested at the Indiana University Cyclotron Facility in summer 2003 using low intensity, 200 MeV protons

- 6x6 mm² beam profile
- beam scanned vertically, horizontally, and at angle to prototype

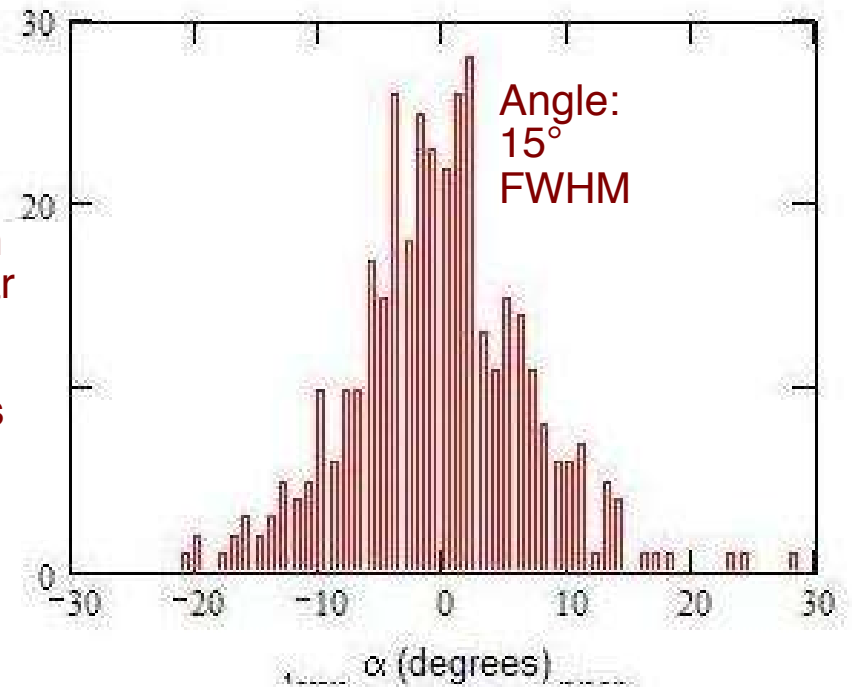

IUCF 200 MeV proton beam

Test results:

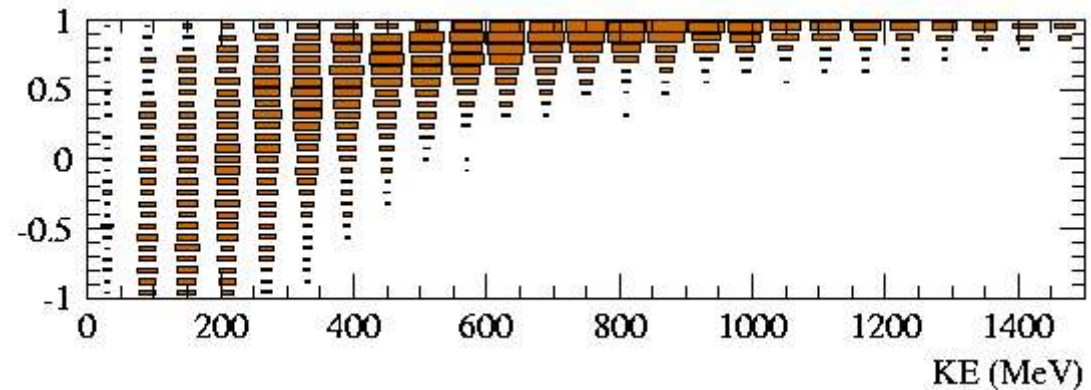

light seen
from near
proton
tracks:
 17 ± 2 PEs

Measuring muons from CCQE interactions

- Low energy muons contained in Vertex Detector and veto
- Higher energy muons are forward -- stop in Muon Rangestack

Range outs in:

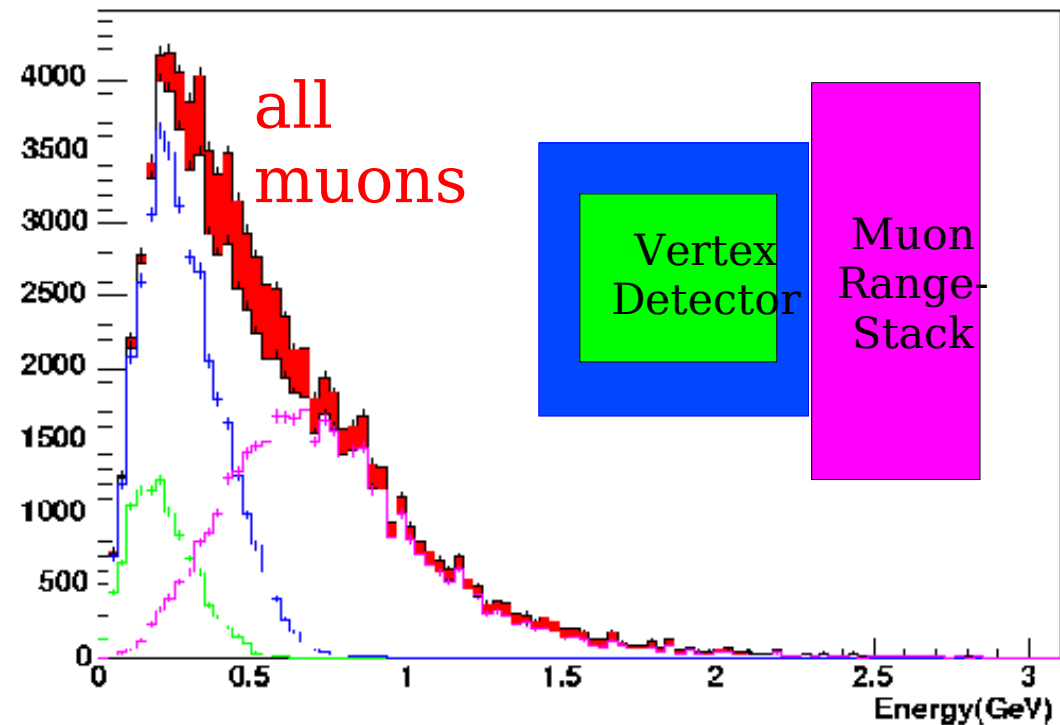

In Vertex Detector
signal region

or

In Vertex Detector
signal region + veto

or

In Vertex Detector
+ Muon Rangestack

Bartoszek Engineering

- Muon Rangestack is designed to:
 - range out .15 to 1.5 GeV muons with energy resolution of 10%
 - minimizing cost, space, and number of different components
 - well tested and understood design

- 21 pairs of scintillator and iron absorber planes
- four sections with thickness of iron absorber = $0.5'' \times n$ ($n=1$ to 4) in each 1:4 scintillator:iron as lower energy particles range out (and only higher energy particles remain) iron can be thicker while retaining same energy resolution

FINeSSE Detector Simulation and Reconstruction

The FINeSSE detector has been simulated using:

- NUANCE for the event generation
- GEANT for the detector simulation
- A Hough-transform-based reconstruction package

FINeSSE Detector Simulation and Reconstruction...

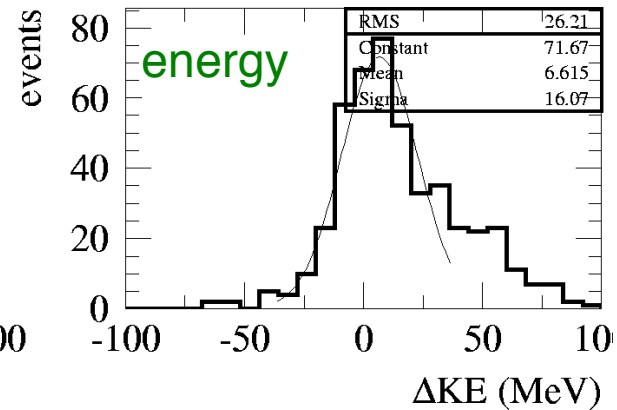

Simulation and reconstruction of 50-500 MeV protons and muons:

- $\Delta E \sim 15\text{MeV}$

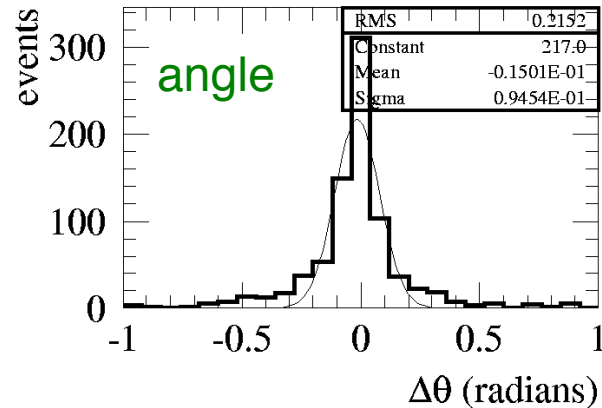

protons

muons

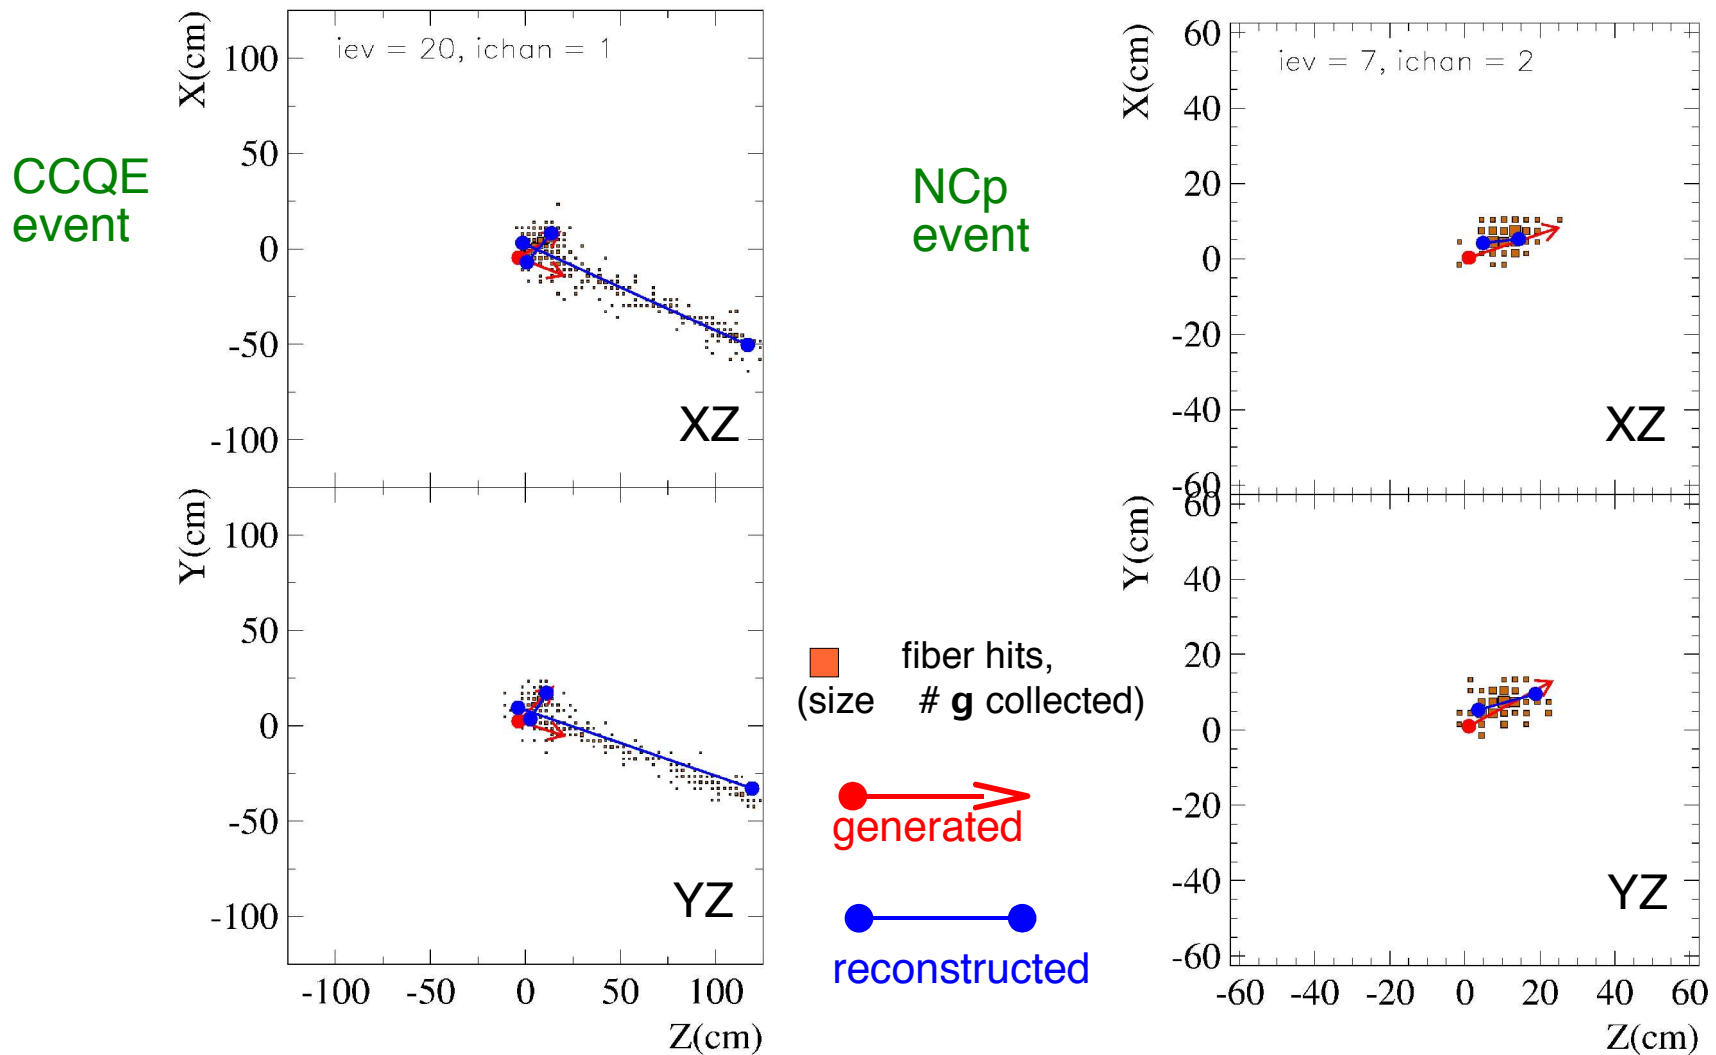

- $\Delta\theta \sim 6^\circ$

FINeSSE Detector Simulation and Reconstruction...

simulated hits and reconstructed tracks in the Vertex Detector

Simulation of R(NC/CC) measurement

NCp and CCQE cuts
for R(NC/CC)
measurement:

| cut # | NCp cuts | CCQE cuts |
|-------|--------------------------------|------------------------------------|
| 0 | edge distance $> 15\text{cm}$ | edge distance $> 15\text{cm}$ |
| 1 | # 3d tracks = 1 | # 3d tracks.eq.2 |
| 2 | $dE/dx(p) > 2.5$ | $dE/dx(p) > 2.5, dE/dx(\mu) < 2.5$ |
| 3 | $\theta(p) > 0.5$ | $\theta(p) + \theta(\mu) > 1.5$ |
| 4 | no "late" light in vertex det. | no "late" light in vertex det. |
| 5 | no veto or muon stack energy | low "remaining" energy |

Resulting
NCp and CCQE
efficiencies
from a 215k event

FINeSSE Sensitivity to Δs

A fit to the simulated data was performed to estimate the precision of a Δs measurement with FINeSSE:

Included the effects of:

- statistical errors
- systematic errors due to...
- NCn ($\nu n \rightarrow \nu n$) scattering misid
- scattering from free protons
- uncertainties in efficiencies
- Q^2 reconstruction
- nuclear model uncertainties
- form factor uncertainties

Results:

$$\sigma(\Delta s) = \pm 0.04 \text{ (stats. and exp. sys.)} \\ = \pm 0.025 \text{ (f. f. sys)}$$

Recall:

BNL E734 $\Delta s = -0.21 \pm 0.10 \pm 0.10$
polarized DIS $\Delta s = -0.14 \pm 0.03$

$$R_\nu(NC/CC) = \frac{\sigma(\nu_\mu p \rightarrow \nu_\mu p)}{\sigma(\nu_\mu n \rightarrow \mu p)}$$

NC/CC ratio: (vs Q^2)

A precise, theoretically robust measurement of Δs via
Neutrino-scattering

Working to improve on this by improving detection techniques:

- 1) Oil studies in “Scibath”
- 2) Phase II: Liquid Argon TPC

- Identifying neutrons!
 - Dominant systematic in measuring neutrino-proton cross section
 - $(\nu p \rightarrow \nu p)/(\nu n \rightarrow \nu n)$ is more sensitive to Δs
- Measure short tracks (low Q^2) – good resolution
- Eliminate error on correction for scattering on free protons (no free protons!) (LArTPC only)

ν vs $\bar{\nu}$ running allows for sensitivity to Δ s and other form factors

$R(\text{NC}/\text{CC})$ vs Q^2 f
with different values of
 F_1^s, F_2^s, G_A^s, M_A

Use shape change in
neutrino versus
anti-neutrino running
to extract other
form factors and
understand systematics

Considering ν and $\bar{\nu}$ running

Rich energy region: different channels turning on and off

A lot going on
at low energies:

quasi-elastic
single π

(DIS turning on)

clean beams,
but flux and
cross sections
dropping rapidly
need intense beams!

- Charged Current Quasi-elastic scattering
- Pion Production channels
- Neutral current elastic electron scattering

Quasi-Elastic Scattering

Existing data:

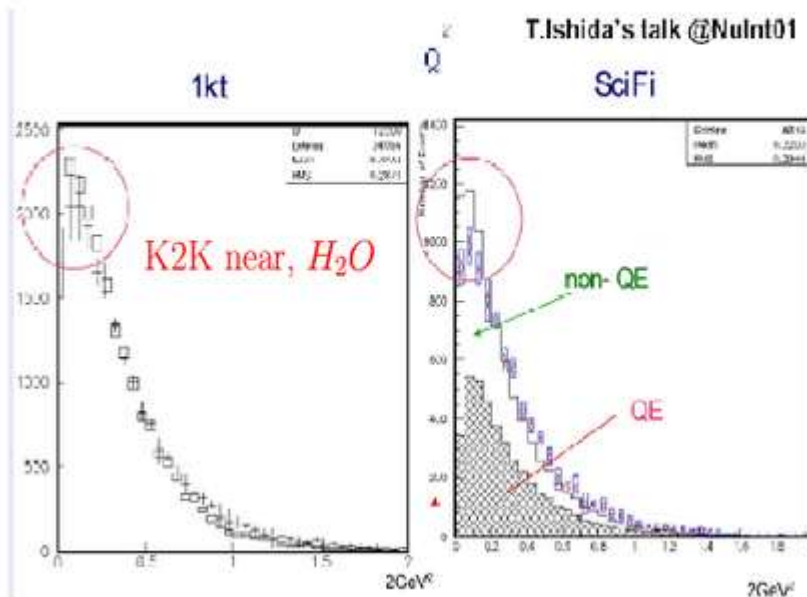

- uncertainties dominated by 15-20% flux errors
- low statistics (largest published data set has ~2500 evts)
- all data below 1 GeV is on light targets (D₂)

↓
use CCQE samples to unfold nuclear effects:

- Interesting rollover at low Q^2
- not fully reproduced by any of the MCs
 - same effect seen by K2K near detectors

K. Furuno, NuInt02 proceedings to be published in Nucl. Phys. B.
Baker *et al.*, Phys. Rev. D23, 2499 (1981)

Pauli Suppression effect?
Nuclear Shadowing?

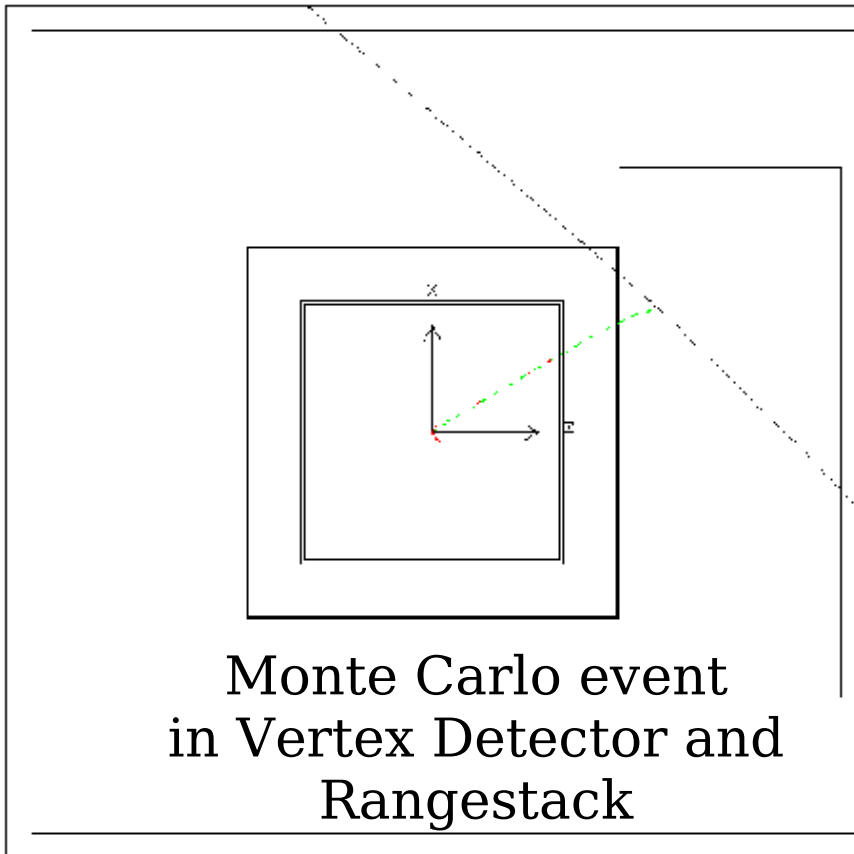

Sam Zeller

Measure CCQE's with fine-grained,
high statistics experiment,
down to low Q^2

~ 150,000 charged current quasi-events
expected in Vertex Detector

very pure sample:
separate $CC\pi^+$, CCQE

see proton
recoil in
Vertex Detector
and range out
muons in
range stack

■ fiber hits,
(size # g collected)

● →
generated

● — ●
reconstructed

Suppression seems to be largest in $CC\pi^+$ sample
Want to easily identify these events

FINeSSE Event Display

Single Pion Production

Resonant Production ($\sim 80\%$)

- resonant channels typically known $\sim 20\text{-}40\%$
- interactions complicated by final state effects (π absorption, charge exchange)
- as in QE's, all data below 1 GeV is on light targets

CC Single Pion Production

Coherent Production ($\sim 20\%$) scatter from entire nucleus...

- overall rate not well known ($\sim 100\%$ uncertainty)
- no data below 2 GeV

x20 variation in recent models
at $E \sim 1$ GeV

distinct kinematics:
forward scattered \mathbf{p}
small energy transfer to target (low Q^2)

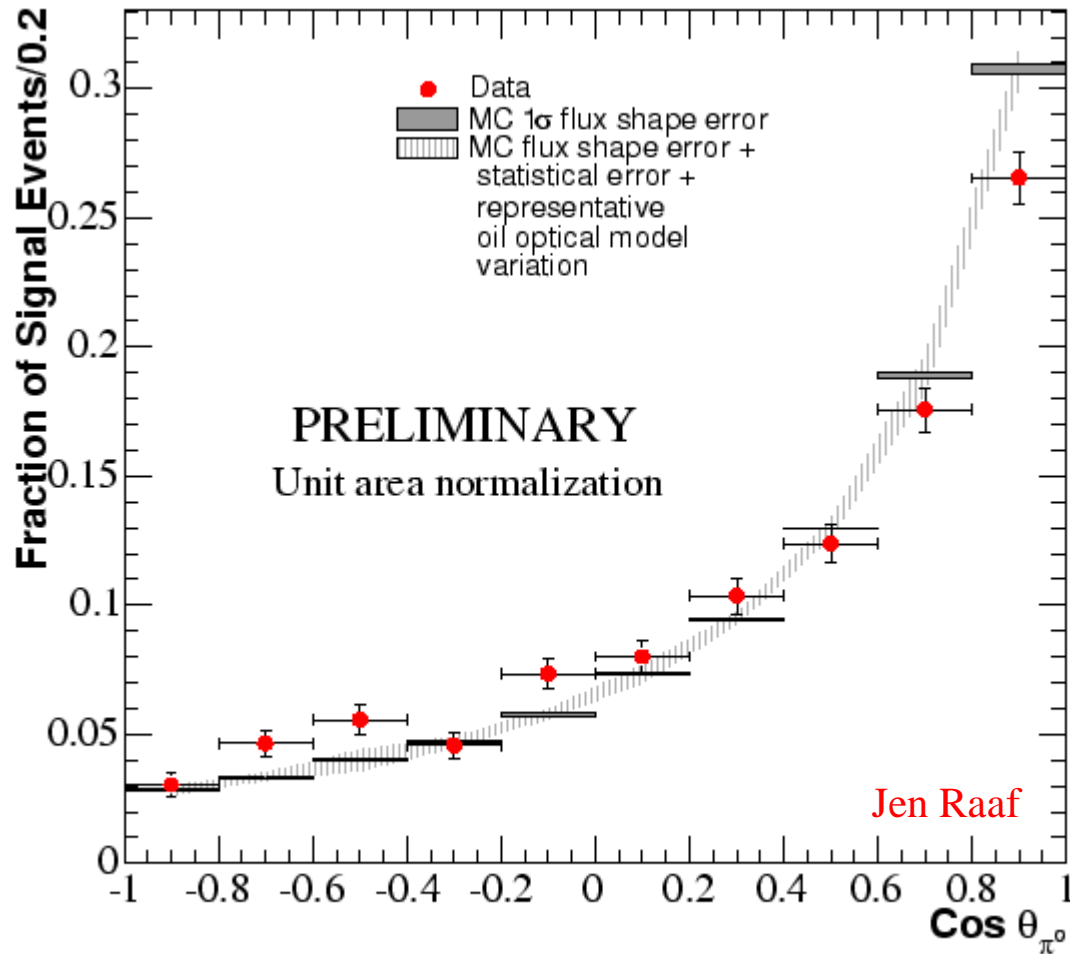

Neutral current π^0 production: significant background for present and future $\nu_u \rightarrow \nu_e$ oscillation searches

- very little data
- spread in model descriptions

Preliminary MiniBooNE data suggests there may be surprises here too!

Neutral current π^0 s in FINeSSE

Fine-grained detector
can separate out these
events well

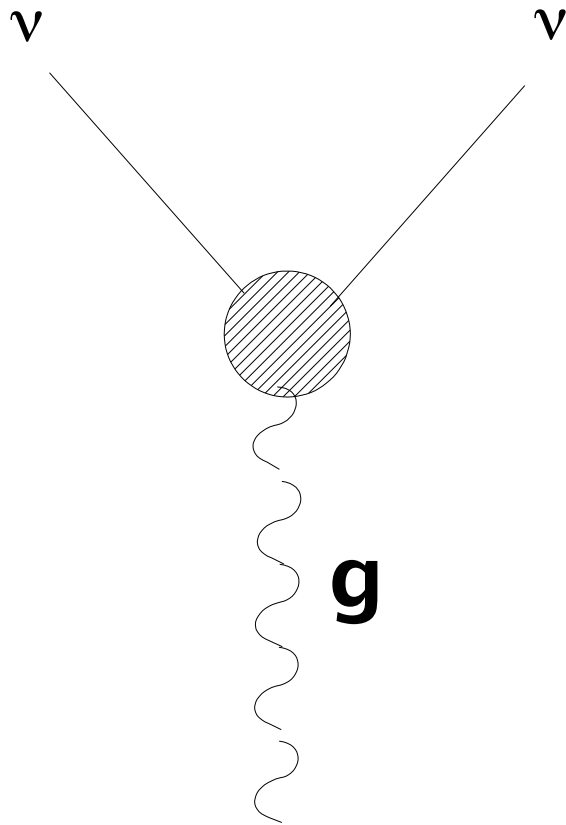

Counting multiple
rings is harder than
looking for little blobs

Even better in Liquid Argon TPCs:
excellent spatial resolution: separating single pion
production from other channels

νe scattering: neutrino magnetic moments

Increase in overall cross section

$$\sigma_{\text{tot}} = \sigma_{\text{weak}} + \sigma_{\text{EM}}$$

massive neutrinos imply existence of ν_R

Weak and EM Contributions to the ν -e Cross Section

Limits set from experiment:

Electron ν magnetic moment: $\mu_{\nu_e} \rightarrow 1.0 - 1.5 \cdot 10^{-10} \mu_B$

- Preliminary measurement from MUNU
- SuperK shape fit

Muon ν magnetic moment: $\mu_{\nu_\mu} \rightarrow 6.8 \times 10^{-10} \mu_B$

- LSND experiment: combined measurement of electron and muon neutrino magnetic moment using total $\nu_e \rightarrow \nu_e$ cross section

How is this different from n_e searches? (already set better limits)

- solar ν_e measures μ_2
- reactor $\bar{\nu}_e$ measures primarily μ_1 and μ_2
- accelerator ν_μ s would measure μ_1 , μ_2 , and μ_3

Tau ν magnetic moment $\mu_{\nu_\tau} \rightarrow 10^{-9} \mu_B$

- SuperK & SNO bounds for all neutrinos

Different beyond-the-Standard-Model theories
predict different sizes for this neutrino magnetic moment

Minimally Extended Standard Model

$$\sim 3 \times 10^{-19} \mu_B$$

SUSY models: left-right supersymmetric models

$$\mu_{\nu_e} \rightarrow 5.34 \times 10^{-15} - 10^{-16} \mu_B$$

$$\mu_{\nu_\mu} \rightarrow 1.13 \times 10^{-12} - 10^{-13} \mu_B$$

$$\mu_{\nu_\tau} \rightarrow 1.9 \times 10^{-12} \mu_B$$

Large Extra Dimensions

$$\mu_\nu \rightarrow 1.0 \times 10^{-11} \mu_B$$

order of
magnitude
lower than
present limits

ν_e scattering with FINeSSE

- high resolution detector to get clean sample
- low electron recoil threshold
- lots of neutrinos

FINeSSE “scibath” detector:
forward electron shower

FINeSSE Phase 2 LArTPC

FINeSSE physics:

- measure strange spin of the proton
- suite of low energy neutrino cross section measurements

Working to understand in detail how well we can do
but all the ingredients are there....
for the first time.

- High intensity beams → **high event rates**
- Minimize **flux uncertainties**
 - 15% in the past → 5% expected by MiniBooNE and less by MINOS/MINERvA
- Minimize **background contamination**
 - low energy neutrino spectrum (below DIS turn-on and with small high energy tail)
 - fine-grained detector → good final state separation

Beam

Detector

Possibilities at Brookhaven

Neutrino experiments need lots of beam....

g-2 muon
storage ring

AGS: high intensity machine

→ **can re-invent the short experimental run for neutrino physics!**

Running concurrently with RHIC (80 hours/wk)

At intensities and energies (8 GeV) anticipated for RSVP

30TP/second in 2008, just before RSVP turns on

Experimental needs: 1.5×10^{20} protons on target total...

4 month run!

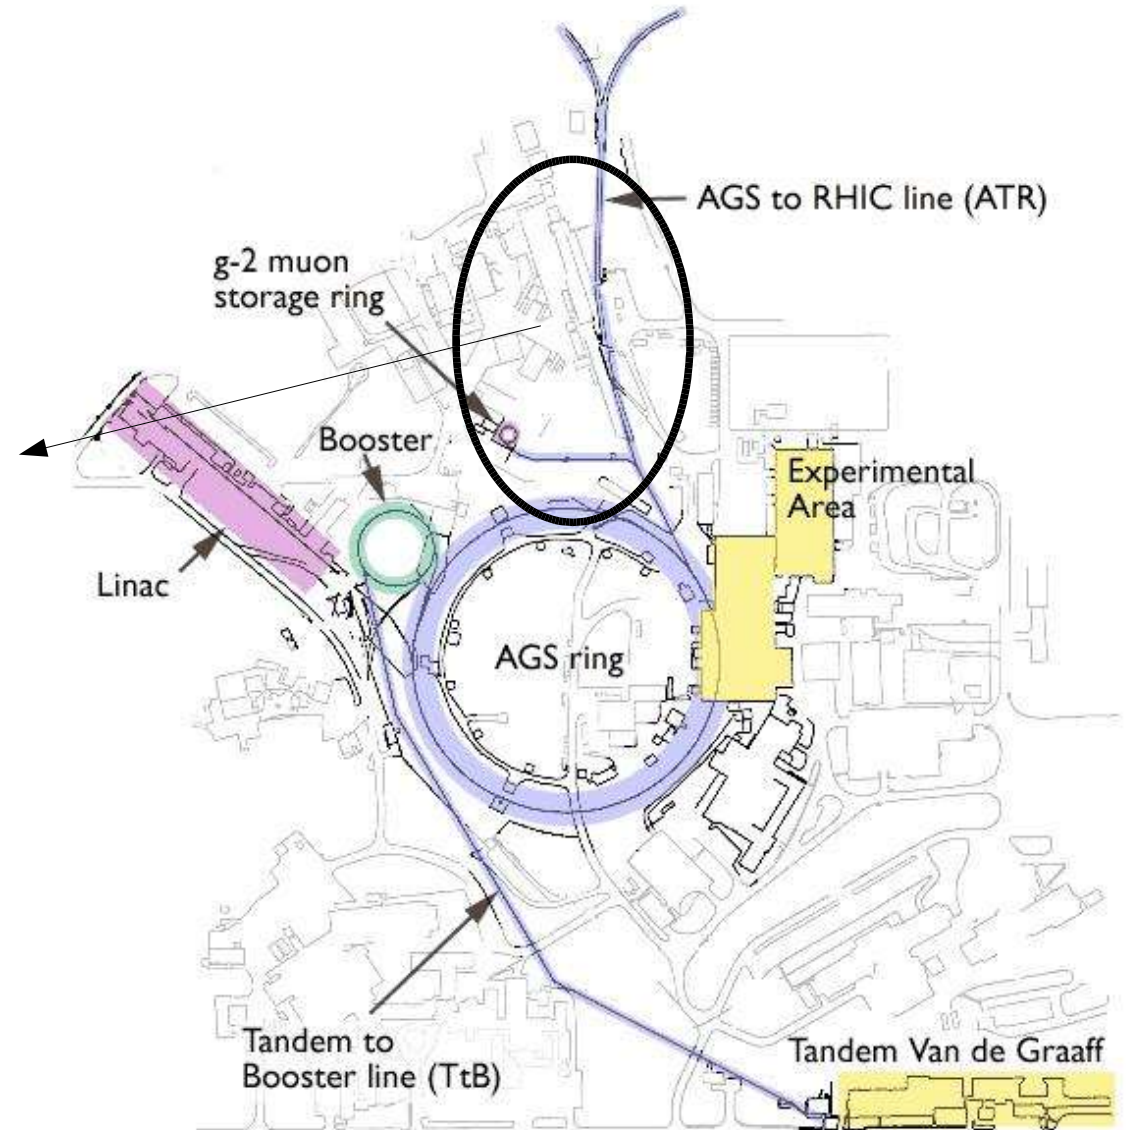

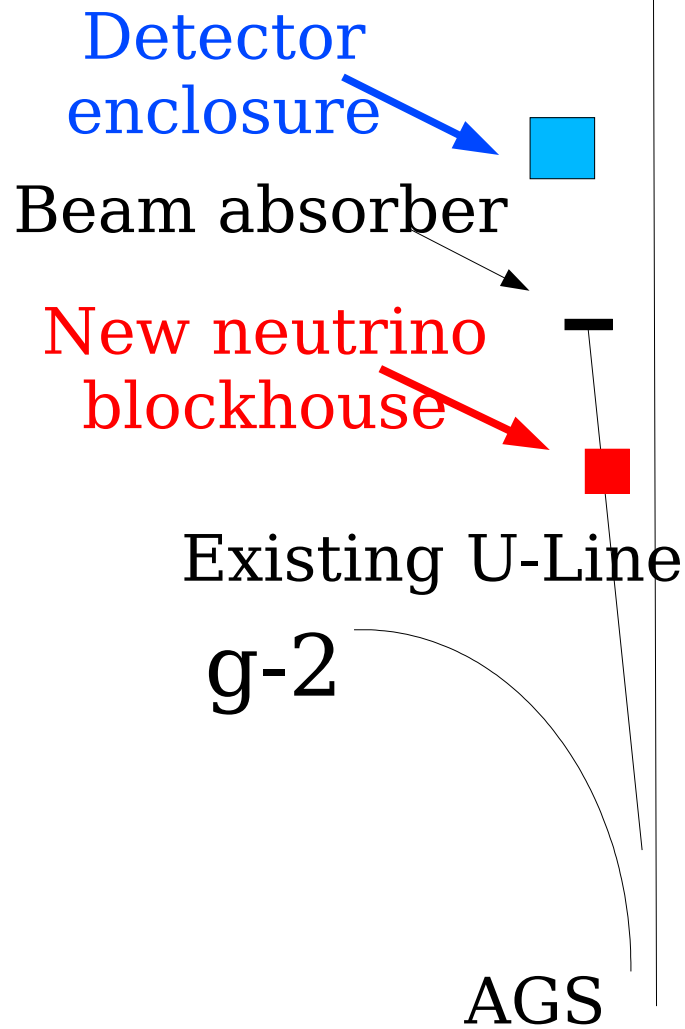

things to be sorted out: extracting high intensity, lower energy beam....

tandem to
Booster line (TtB)
